## Assessment of Haddock on Eastern Georges Bank

S. Gavaris and L. Van Eeckhaute

Department of Fisheries and Oceans  
Biological Station  
St. Andrews, New Brunswick  
E0G 2X0

<sup>1</sup> This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

<sup>1</sup> La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

## Abstract

Haddock catches from eastern Georges Bank fluctuated around 5,000 tons from the early 1980s to 1993. Under restrictive management measures, catches declined from 6,366 t in 1991 to a low of 2,111 t in 1995, then increased again to 3,720 t, 2,733 t and 3,696 t in 1996, 1997 and 1998 respectively. Over half of the 1998 catch weight was comprised of haddock from the 1992 and 1993 year-classes. The trend in ages 3-8 abundance from surveys increased from 1992 to 1996 and has fluctuated since then. Surveys indicate that the 1996 year-class may be comparable to the moderate 1983, 1985, 1987 and 1992 year-classes. The 1997 year-class is weaker and preliminary indications suggest that the 1998 year-class may be strong.

Population biomass for ages 3-8 has steadily increased from near historic low levels of 6,737 t in 1993 to 26,836 t in 1999. The recent increase, due principally to the 1992 year-class, but also supported by the 1991 and 1993 year-classes, was enhanced by increased survivorship of young haddock resulting from reduced capture of small fish in the fisheries. The continuing increase is being sustained by the 1996 year-class. The abundance of the 1996 year-class was estimated at about 16 million. The 1995 and 1997 year-classes appear weaker at about 6 million. The exploitation rate for fully recruited ages 4-8 has consistently been below the  $F_{0.1}$  target of 20% since 1995. Reduced fishing mortality in recent years has resulted in increased survival of incoming year-classes and greater abundance at older ages.

Projected total Canada/USA yield at  $F_{0.1} = 0.25$  in 1999 would be about 6,300 t. If fished at  $F_{0.1}$  in 1999, the biomass for ages 3-8 is projected to increase from 26,836 t to 27,430 t at the beginning of 2000. Ages 3-7 should comprise about 90% of the total yield in 1999 with all these year-classes contributing almost equally. A projected total Canada/USA catch of 4,000 t in 1999, about what was caught in 1998, results in a negligible risk that fishing mortality rate will exceed  $F_{0.1}$  and that the biomass for ages 3-8 will decrease. At this yield, there is a risk of about 50% of not achieving 10% biomass increase and a risk of over 90% of not achieving 20% biomass increase.

## Résumé

Dans la portion est du Banc Georges, les captures d'aiglefin réalisées du début des années 1980 jusqu'en 1993 ont fluctué autour de 5 000 tonnes. Sous mesures de gestion restrictives, les captures sont passées de 6 366 t en 1991 à un minimum de 2 111 t en 1995, puis sont remontées respectivement à 3 720 t, 2 733 t et 3 696 t en 1996, 1997 et 1998. Plus de la moitié du poids des prises en 1998 était composée d'aiglefin des classes de 1992 et de 1993. Selon les relevés, il y a eu une tendance à la hausse de l'abondance des classes d'âges 3 à 8 entre 1992 et 1996, qui a ensuite fluctué. Les relevés indiquent que la classe de 1996 pourrait être comparable aux classes d'abondance moyenne des années 1983, 1985, 1987 et 1992. La classe de 1997 est plus faible, mais selon les constatations préliminaires, celle de 1998 pourrait être forte.

La biomasse de la population des classes d'âge 3 à 8 s'est accrue de façon régulière, partant d'un minimum historique de 6 737 t en 1993 pour atteindre 26 836 t en 1999. L'accroissement récent, attribuable en gros à la classe de 1992, mais en partie aussi à celles de 1991 et de 1993, s'est amplifié grâce à une meilleure survie des jeunes aiglefins, qui tient à la baisse des captures de petits poissons. Cet accroissement continu est alimenté par la classe de 1996, dont l'effectif a été estimé à environ 16 millions. Celui des classes de 1995 et de 1997 semble plus faible, aux environs de 6 millions. Depuis 1995, le taux d'exploitation des classes d'âges pleinement recrutées de 4 à 8 a régulièrement été sous le niveau cible  $F_{0.1}$  de 20 %. Une baisse de la mortalité par pêche ces dernières années a contribué à augmenter la survie des classes d'âge non encore recrutées, et l'abondance des poissons plus âgés.

En 1999, la récolte totale prévue Canada/États-Unis au niveau  $F_{0.1} = 0,25$  est d'environ 6 300 t. Si la pêche s'effectue au niveau  $F_{0.1}$  en 1999, on prévoit que la biomasse des classes d'âges 3 à 8 augmentera de 26 836 t à 27 430 t au début de l'an 2000. Les classes d'âge 3 à 7 devraient former 90 % de la récolte totale en 1999, chacune contribuant à peu près également. Les risques sont négligeables que la récolte Canada/États-Unis de 4 000 t escomptée en 1999, l'équivalent de celle de 1998, entraîne une hausse du taux de mortalité par pêche supérieure au niveau  $F_{0.1}$  et une baisse de la biomasse des classes d'âges 3 à 8. Avec une telle récolte, le risque est de 50 % environ de ne pas atteindre une hausse de la biomasse de plus de 10 % et il est de 90 % de ne pas atteindre une hausse de 20 %.

## **Introduction**

Since 1990, Canada has used eastern Georges Bank, fishery statistical unit areas 5Zej and 5Zem (Figure 1), as the basis for a management unit (Gavaris 1989), referred to as 5Zjm for brevity. Results from the previous assessment (Gavaris and Van Eeckhaute 1998) indicated an increase in total biomass from 12,000 metric tonnes (t) in 1993 to almost 29,000 t at the beginning of 1998 and a decline in exploitation rate to below  $F_{0.1}$  since 1995, resulting in increased survival of recent year-classes. However, current abundance remains below historical levels observed during the 1930's to mid 1950's when biomass was over 60,000 t and recent year-class sizes have also been well below historical levels.

In this assessment update, we included the latest information from the 1998 Canadian and USA fisheries and made minor revisions to the 1997 data. Results from the Department of Fisheries and Oceans, Canada (DFO) survey in the spring of 1999 and the National Marine Fisheries Service, USA (NMFS) surveys in the spring and fall of 1998 were incorporated. Methods similar to those used in the last assessment were applied to the updated information.

## **The Fishery**

### ***Commercial Catches***

The haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982). For details on the historical aspects of the Georges Bank haddock fishery see Gavaris and Van Eeckhaute (1998).

Under restrictive management measures, combined Canada/USA catches declined from about 6,400 t in 1991 to a low of about 2,100 t in 1995, then increased to about 3,700 t in 1996, 2,700 t in 1997 and 3,700 t in 1998 (Table 1, Figure 2). Greater catches in the late 1970s and early 1980s, ranging up to 23,189 t in 1980, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated at about 5,000 t during the mid to late 1980s.

Catches during the 1930s to 1950s ranged between 15,000 t and 40,000 t (Schuck 1951, R. Brown pers. com.), averaging about 25,000 t (Figure 3). Records of catches by unit area for the early 1960s period have not been located, however based on records for Subdivision 5Ze, catches probably attained record high levels of about 60,000 t. Since the early 1970s catches have been substantially lower, generally fluctuating between 5,000 t and 10,000 t.

As in 1995 to 1997, Canadian catches in 1998 of 3,371 t were below the quota due to closure of the fisheries when the cod quotas were reached. During 1994 to 1998, all Canadian groundfish fisheries on Georges Bank remained closed from January to early June to protect spawning.

All landings were monitored at dockside, and at-sea monitoring by observers resulted in coverage of almost 400 sea days, representing about 10% of the cod and haddock catch. One hundred and fifty-one vessels fished for groundfish on Georges Bank making 770 trips. Comparison of observer samples with port samples did not reveal any persistent patterns to

indicate that discarding or high grading occurred commonly. Discarding and misreporting have been considered negligible since 1992. During 1998, all vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft and fixed gear vessels 45-65 ft operated on individual quotas and fixed gear vessels under 45 ft operated on community quotas administered by local boards (Table 2).

Fishery Sector	1994		1995		1996		1997		1998	
	Quota	Catch	Quota	Catch	Quota	Catch	Quota	Catch	Quota	Catch
Fixed gear <65'	791	784	592	357	1085	919	754	714	915	856
Mobile gear <65'	1439	1206	1268	1175	2280	1713	1625	1451	1984	1997
Fixed gear 65'-100'	30	8	25	0	45	49	32	36	39	39
Mobile gear 65'-100'	30	33	25	27	189	181	32	35	94	93
Vessels >100'	710	290	590	444	921	513	757	573	868	386
Totals	3000	2411	2500	2003	4500	3375	3200	2809	3900	3371

In recent years, the Canadian fishery has been conducted by vessels using otter trawls, longlines, handlines and gillnets (Table 3). Most haddock were caught by otter trawlers and longliners less than 65 ft. The catches by otter trawlers peaked in June while catches by longliners peaked in July (Table 4, Figure 4).

Changes in the way Canadian fishermen are conducting their fishing activities on Georges Bank have occurred in recent years because of the low cod quota and the need, therefore, to avoid cod. Avoidance of cod has been especially difficult for the fixed gear fleet whose gear has a higher catchability for cod than haddock. In an effort to avoid cod, they fished in the deeper water of the Fundian Channel where cod were not as abundant and avoided the shallower bank waters where cod abundance was higher. Mobile gear is less selective for cod than the fixed gear and they did not have as much difficulty keeping their cod catch to minimal levels.

USA catches for 1998 were derived from logbooks coupled with dealer reports, as was done for 1994-97. Effort in the USA fishery was regulated using closed areas and Days-at-Sea limits (Table 2). To curtail targeting of haddock, a 500 lb trip limit was introduced in 1994 and raised to 1,000 lb in July 1996. The trip limit resulted in an increase in the discard rate. In September 1997, the limit was raised to 1,000 lb per day and a maximum of 10,000 lb per trip. In September 1998, the limit was further raised to 3,000 lb per day and 30,000 lb per trip. The plan for the 1999 fishing year is to establish a limit of 2,000 lb/day (maximum of 20,000 lbs/trip) beginning on May 1, 1999 which will be adjusted upward if the industry is significantly under the established target TAC. The combination of area closures, effort restrictions, and trip limits has precluded most operators from making long trips to 5Zjm, with the result that USA catches from 5Zjm have been low since 1993. While Area II remained closed in 1998, landings from 5Zjm, which come exclusively from tonnage classes 3 and 4 otter trawlers (Table 5), increased to 311 t and discards declined to 14 t (Table 1 and 6) because the day and trip possession limits were increased.

### ***Size and Age Composition***

The size and age composition of the 1998 Canadian fishery was characterised by port and at sea samples from all principle gears and all seasons (Figure 4) and were applied to the 1998

catch (Table 7) similarly as in the previous year (Gavaris and Van Eeckhaute 1998). The size composition of the catch in the Canadian fisheries peaked at 53 cm (21 in) for otter trawlers and at 57 cm (22 in) for longliners (Figure 5) which is a change from previous years when these two gears caught more similarly sized fish. This may be a result of the longliner's switch to fishing in deeper water to avoid cod. Gillnetters caught few haddock but they were larger. No sampling was available for discards of groundfish by-catch in the Canadian scallop fishery though in previous years the amount caught has not been large.

With low landings of haddock in the USA fishery, available port samples were inadequate to characterise the size and age composition of the landings. The age composition of the Canadian otter trawler tonnage class 3 or less fishery were used here. Sea sampling for discards was limited but was used to obtain the discards at age.

Survey and commercial otoliths were read by L. Van Eeckhaute for DFO and by N. Munroe for NMFS. Results of intra-reader and between reader agreement tests for the 1998 DFO spring survey and an intra-reader test using the Canadian commercial sampling material for the DFO reader (Appendix A) indicate that age data are consistent.

The updated 1997 and the new 1998 catch at age by quarter (Table 8) was used to augment the 1969-96 results reported by Gavaris and Van Eeckhaute (1998). Annual catch at age and average fishery weight at age are summarized in Tables 9 and 10.

Over half of the 1998 catch weight was comprised of haddock from the 1992 (age 6) and 1993 (age 5) year-classes (Table 8,9; Figure 6). In contrast to pre-1994, few haddock of ages 2 and 3 were caught in 1998, due in part to the type of gear used and to avoidance of areas with small fish (Figure 7). In comparison to the age composition of the catch during earlier periods, age groups 4-7 were well represented.

## **Abundance Indices**

### ***Commercial Catch Rates***

Catch rate trends from the Canadian commercial fishery were compiled for selected trips where cod, haddock and pollock comprised over 90% of the total catch of only those vessels which fished in 5Zjm during 1994 and reported more than 1 t of landings. Catch rates by tonnage class 2 and 3 otter trawlers and longliners showed an increasing trend from 1993 to 1995 and remained relatively stable but variable from 1996 through 1998 (Figure 8). Otter trawl catch rates were relatively high in June of 1998, decreased in the fall and increased again in December. Longliner catch rates for tonnage class 2 increased markedly through the 1998 season while those for tonnage class 3 decreased. Changes to regulations, gear modifications and varying fishing practices in recent years make comparison of catch rates from year to year difficult to interpret. Therefore, these were not used as indices of abundance.

### ***Research Surveys***

Groundfish surveys of Georges Bank have been conducted by NMFS each fall (Oct.-Nov.) since 1963 and each spring (Mar.-Apr.) since 1968, and by DFO each spring (Feb.-Mar.) since 1986. All these surveys use a stratified random design (Figures 9 and 10). For the NMFS

surveys, two vessels have been employed and there was a change in the trawl door in 1985. Conversion factors (Table 11), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent. Additionally, two trawl nets were used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock.

The distribution of catches for the most recent surveys of each series was similar to the distribution over the previous 5 year period (Figures 11, 12 and 13). In spring, adults are more abundant in unit area 5Zej but age 1 fish are distributed broadly over unit areas 5Zej and 5Zem (Figures 11 and 12). In fall, adult haddock are more concentrated in the deeper waters along the slopes of the Northeast Peak and the Northeast Edge, however, age 1 fish remain somewhat more widespread (Figure 13).

Haddock of all ages are more abundant east of the USA/Canada boundary line during all three surveys. The percent of biomass, ages 3-8, on the Canadian side of 5Zjm from the three surveys was summarised for the most recent years. During the NMFS fall survey, almost all of the biomass occurred on the Canadian side. During the DFO spring survey, generally conducted in late February, most of the biomass was on the Canadian side although the percentage was lower in 1992-93. During the NMFS spring survey, generally conducted in late March, the percentage on the Canadian side was typically lower but these results were more variable

Year	Percentage of biomass on Canadian side		
	Feb.-Mar.	Mar.-Apr.	Oct.-Nov.
	DFO	NMFS	NMFS
1992	68	78	100
1993	67	43	99
1994	99	100	100
1995	98	62	100
1996	96	17	100
1997	92	93	100
1998	100	78	100
1999	98	N/A	N/A

Age specific abundance patterns from the three surveys track year-class strengths fairly well (Tables 12, 13 and 14; Figure 14). Some year effects are evident as well, for example, the low spring catches observed for both the 1997 DFO and NMFS surveys. The trend in ages 3-8 abundance from surveys increased from 1992 to 1996 and has fluctuated with a moderate general increasing trend since then (Figure 15). Abundance peaked at record highs during the early 1960s. After declining to a record low in the early 1970s, it peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak.

Survey results for ages 1 and 2 indicate that the abundance of the 1996 year-class may be comparable to the moderate 1983, 1985, 1987 and 1992 year-classes (Figure 16). These year-classes were considerably smaller than the strong 1975 and 1978 year-classes and the very strong

1962 and exceptional 1963 year-classes. The 1997 year-class is weaker but first indications for the 1998 year-class suggest it may be moderate to strong.

Average weights at age of haddock from the 1989 to 1991 year-classes were higher than adjacent year-classes in both the surveys (Figure 17) and the commercial fisheries (Figure 18), giving the false impression of a declining trend in recent years. The method of calculation of the weights at age from the DFO spring survey were given in Gavaris and Van Eeckhaute (1998) and were derived from actual weights observed during the survey and weighted by population numbers at length and age (Table 15). Fishery weights at age (Table 10; Figure 18) are derived from a length-weight relationship (Waiwood and Neilson 1985). In some cases, the mean weight at age in the catch is larger than the population mean weight at age at the beginning of the following year for the same cohort. This may be attributable to the different methods used to derive the two sets of weights. The use of eviscerated weights in length-weight equations would reduce variability due to gonad and stomach content effects and sampling size and ensure consistency between population and fishery weights at age.

## Estimation of Stock Parameters

### *Calibration of Virtual Population Analysis (VPA)*

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey abundance information. An investigation of model formulations and model assumptions was conducted by Gavaris and Van Eeckhaute (1998) where details of model equations and the objective function are provided. The model formulation adopted assumed that the random error in the catch at age was negligible. The errors in the abundance indices were assumed independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate,  $M$ , was assumed constant and equal to 0.2. Similar model assumptions and methods were applied to the updated information here. Minor differences in the handling of zero terminal catches for a year-class were implemented as a refinement to the software to afford more flexibility. Additionally, both analytical and bootstrap statistics of the estimated parameters were derived. For consistency with the risk analysis, bias adjusted VPA results were based on bootstrap statistics (Efron and Tibshirani 1993).

The VPA used quarterly catch at age,  $C_{a,t}$ , for ages  $a = 0, 1, 2 \dots 8$ , and time  $t = 1969.0, 1969.25, 1969.5, 1969.75, 1970.0 \dots 1998.75$ , where  $t$  represents the beginning of the time interval during which the catch was taken. The VPA was calibrated to bottom trawl survey abundance indices,  $I_{s,a,t}$ , for

$s =$  DFO spring, ages  $a = 1, 2, 3 \dots 8$ , time  $t = 1986.16, 1987.16 \dots 1998.16, 1999.0$

$s =$  NMFS spring (Yankee 36), ages  $a = 1, 2, 3 \dots 8$ , time  $t = 1969.29, 1970.29, 1971.29, 1972.29, 1982.29, 1983.29 \dots 1998.29$

$s =$  NMFS spring (Yankee 41), ages  $a = 1, 2, 3 \dots 8$ , time  $t = 1973.29, 1974.29 \dots 1981.29$

$s =$  NMFS fall, ages  $a = 0, 1, 2 \dots 5$ , time  $t = 1969.69, 1970.69 \dots 1998.69$

Since forecast projections were required for the entire year 1999, the DFO spring survey in 1999 was designated as occurring at time 1999.0 instead of 1999.16. The NMFS fall survey captures young of the year and that information is included as 0 group, but older haddock appear

less available during this season. Survey indices for older ages where catches were sparse and there were frequent occurrences of zero catches were not included. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. During years when discarding was high, survey information was used along with interviews to obtain estimates of the USA catch. This lack of complete independence between catch and survey data does not influence population estimates but may deflate variance estimates marginally.

The population abundance estimates show a large relative error and substantial bias at ages 1 and 2 while the relative error for other ages is about 30% and the bias is small (Table 16). The average magnitude of residuals is large and though several large residuals can be identified, the respective observations do not appear influential and should not impact parameter estimates of current abundance (Figures 19-23). Some patterns in the residuals (by cohort and by age) merit further investigation.

### ***Retrospective Analysis of Calibrated VPA***

Results from assessments for several other stocks have identified a discrepancy between past estimates of stock status and current estimates using additional data (retrospective pattern). Results for this stock indicate that this assessment does not suffer from a retrospective pattern. Figure 24 tracks successive estimates of year-class abundance at age and shows that estimates are fairly stable although there is sometimes a substantial change after the first estimate of a year-class when more data becomes available, as evidenced for the 1992 and 1996 year-classes. There were no trends of concern in the 3+ biomass pattern and the 4+ F when weighted by population numbers (Figure 25).

A Canadian quota of 3,900 t in 1998 was expected to result in a negligible chance of exceeding  $F_{0.1}$  and an 80% chance of getting 20% growth in the stock. The Canadian catch in 1998 was about 3,400 t and resulted in a fishing mortality about 65% of  $F_{0.1}$  and an increase in ages 3-8 biomass of about 24%.

### **Stock Status**

The results from the calibrated VPA were considered appropriate on which to base the status of the stock. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias and used to construct the history of stock status (Tables 17-18). This approach for bias adjustment, in the absence of an unbiased point estimator with optimal statistical properties, was considered preferable to using the biased point estimates (O'Boyle 1998). The weights at age from the DFO spring survey (Table 15) were used to calculate beginning of year population biomass (Table 19). A weight of 2.4 kg, which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. For 1969-85, the 1986-95 average weight at each age was used.

Population biomass (ages 1-8) has steadily increased from near historic low levels of about 11,000 t in 1993 to over 30,000 t at the beginning of 1999 (Figure 26). The recent increase, due principally to the 1992 year-class, but also supported by the 1991 and 1993 year-classes, was enhanced by increased survivorship of young haddock from reduced capture of small fish in the fisheries. The continuing increase is being sustained by the 1996 year-class. The biomass trend

for ages 3-8 is similar with a 24% increase from 1998 to 1999 due largely to recruitment of the 1996 year-class.

The strength of the 1996 year-class was estimated to be about 16 million at age 1, comparable to the 1983, 1985, 1987 and 1992 year-classes, while those during 1988-90 were less than 3 million (Figure 27). The 1991 and 1993 year-classes were estimated at about 7 and 10 million respectively while the incoming 1995 and 1997 year-classes appear to be relatively weak at about 6 million. Preliminary indications for the 1998 year-class indicate that it may be strong at up to about 40 million recruits.

Population biomass during the late 1970s and early 1980s was considerably higher, ranging to almost 50,000 t, due to recruitment of the strong 1975 and 1978 year-classes whose abundance was estimated at about 50 million. However, biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two year-classes were fished intensely at a young age.

Exploitation rate for fully recruited ages 4-8 has consistently been below 20%, equivalent to  $F_{0.1} = 0.25$ , since 1995 (Figure 28). Historically, exploitation rate has generally exceeded  $F_{0.1}$  and showed a marked increase between 1989 and 1993 to almost 50%, the highest level observed. Reduced fishing mortality in recent years has resulted in increased survival of incoming year-classes. The number of haddock of the 1992 year-class surviving to age 6 was about three times that of the equally abundant 1983 year-class, and about the same as that of the 1975 or 1978 year-classes, which were more than 3 times as abundant (Figure 29). In both absolute numbers and percent composition, the population structure displays a broad representation of age groups, reflecting improved recruitment and lower exploitation (Figure 30).

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as a convenient age of first recruitment to the fishery. In most years since 1969, the bulk of the biomass gain was attributable to somatic growth but in years of good recruitment, about half the biomass gain was due to incoming recruits at age 2 (Figure 31). Surplus production is defined as the gains in fishable biomass which are in excess of the needs to offset losses from natural mortality. When the fishery yield is less than the surplus production, there is a net increase in the population biomass. Since 1993, surplus production has exceeded or been about equal to the fishery yield resulting in net biomass growth (Figure 32).

## **Fishery Reference Points**

### ***Yield per Recruit***

The yield per recruit analysis was updated in Gavaris and Van Eeckhaute (1998). We adopted those results here.

### ***Stock and Recruitment***

The age composition of the catch for Georges Bank haddock (Clark et al 1982) was used with catch statistics from unit areas 5Zej and 5Zem to approximate the catch at age for the 5Zjm

management unit for the period between 1930 and 1955. This was considered adequate in order to reconstruct an illustrative population analysis, which is suitable for comparing productivity. The results indicated that the current total biomass was less than a third of the average sustained over those two decades (Figure 33).

The pattern of recruitment against adult biomass indicates that the chance of a strong year-class is significantly reduced for biomass below about 40,000 t (Figure 34). Since 1969, only the 1975 and 1978 (and possibly the 1998) year-classes have been near the average abundance of year-classes observed during that historic period. Examination of the recruits per spawning biomass ratio suggests that egg/larval survivorship for several years during the 1980s may have been lower than the norm (Figure 35). The present survivorship appears comparable to that of the 1930s to 1950s period, supporting the expectation that higher recruitment might result if the biomass increases.

## Prognosis

Yield projections were done using the bias adjusted 1999 beginning of year population abundance estimates. The abundance of the 1999 year-class was assumed to be 6 million at age 0. Partial recruitment to the fishery for ages 1, 2 and 3, fishery weights at age and beginning of year population weights at age were averaged over the previous 4 years for use in the 1999 forecasts (Table 20).

Projected total Canada/USA yield at  $F_{0.1} = 0.25$  in 1999 would be about 6,300 t. If fished at  $F_{0.1}$  in 1999, the biomass for ages 3-8 is projected to increase from 26,836 t to 27,430 t by the beginning of 2000 (Figure 36). Ages 3 to 7 should comprise about 90% of the total yield in 1999, with all these year-classes contributing almost equally.

Uncertainty about year-class abundance generates uncertainty in forecast results. This uncertainty was expressed as risk of achieving reference targets. For example, a combined Canada/USA catch of 4,000 t in 1999, about what was caught in 1998, results in a negligible risk that fishing mortality rate will exceed  $F_{0.1}$  and that the biomass for ages 3-8 will decrease (Figure 37). At this yield there is a risk of about 50% of not achieving 10% biomass increase and a risk of over 90% of not achieving 20% biomass increase.

These uncertainty calculations do not include variations in weight at age, partial recruitment to the fishery and natural mortality, systematic errors in data reporting or model misspecification. Therefore, overall uncertainty would be greater, but these results provide guidelines.

Cod and haddock are often caught together in the Canadian Georges Bank groundfish fisheries. However, their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. This may compromise the joint achievement of objectives.

Table 2. Regulatory measures implemented for the 5Z and 5Zjm fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

	<b>USA</b>	<b>Canada</b>
1977-82	<b>Mesh</b> size of 5 1/8" (140 mm), seasonal spawning closures, quotas and trip limits.	
1982-85	<b>All</b> catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size (43 cm).	<b>First</b> 5Ze assessment in 1983.
1984 Oct.	<b>Implementation of the 'Hague' line .</b>	
1985	<b>5 1/2"</b> mesh size,. <b>Areas</b> 1 and 2 closed during February-May.	
1989		<b>Combined</b> cod-haddock-pollock quota for 4X-5Zc
1990		<b>5Zjm</b> adopted as management unit. <b>For</b> MG < 65 ft. – trip limits with a 30% by-catch of haddock to a maximum of 8 trips of 35,000 lbs per trip between June 1 and Oct. 31 and 130 mm square mesh required. <b>Fixed</b> gear required to use large hooks until June
1991	<b>Established</b> overfishing definitions for haddock.	<b>MG</b> < 65 ft similar to 1990 but mesh size increased to 145 mm diamond.
1992		<b>Introduction</b> of ITQs and dockside monitoring.
1993	<b>Area</b> 2 closure in effect from Jan 1-June30.	<b>OT</b> fishery permitted to operate in Jan. and Feb. <b>Increase</b> in use square mesh.
1994	Jan.: <b>Expanded</b> Area 2 closure to include June and increased extent of area. <b>Area</b> 1 closure not in effect. <b>500</b> lb trip limit. <b>Catch</b> data obtained from mandatory log books combined with dealer reports (replaces interview system). May: <b>6"</b> mesh restriction. Dec.: <b>Area</b> 1,2 closed year-round.	<b>Spawning</b> closure extended to Jan. 1 to May 31. <b>Fixed</b> gear vessels must choose between 5Z or 4X for the period of June to September. <b>Small</b> fish protocol. <b>Increased</b> at sea monitoring. <b>OT</b> > 65 could not begin fishing until July 1. <b>Predominantly</b> square mesh by end of year.
1995		<b>All</b> OT vessels using square mesh. <b>Fixed</b> gear vessels with a history since 1990 of 25t or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in 5Z fishery. <b>ITQ</b> vessel require at least 2t of cod and 8t of haddock quota to fish Georges.
1996	July: <b>Additional</b> Days-at-Sea restrictions, trip limit raised to 1000 lbs.	<b>Fixed</b> gear history requirement dropped.
1997	May: <b>Additional</b> scheduled Days-at-sea restrictions. September: <b>Trip</b> limit raised to 1000 lbs/day, maximum of 10,000 lbs/trip.	<b>Vessels</b> over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels 45-65 ft on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards.
1998	Sept. 1: <b>Trip</b> limit raised to 3000 lbs/day, maximum of 30,000 lbs/trip.	<b>Fixed</b> gear vessels 45-65 ft operated on individual quotas.
1999	May 1: <b>Trip</b> limit of 2,000 lb/day, maximum of 20,000 lbs/trip. To be adjusted upward if industry is significantly under the established target TAC.

Figure 1. Fisheries statistical unit areas in NAFO Subdivision 5Ze.

Figure 2. Nominal catch of haddock in unit areas 5Zjm.

Figure 3. Historic catch of haddock in 5Zjm compared to recent catches.

Figure 4. Haddock catches in 5Zjm by month and gear for the Canadian commercial fishery in 1998 (wide gray bars) with sampling levels (narrow black bars).

Figure 5. Length compositions of the principal Canadian 5Zjm commercial haddock fisheries in 1998.

Figure 6. Total commercial catch at age (numbers) of haddock from unit areas 5Zjm. The bubble area is proportional to magnitude (see Table 9).

Figure 7. Age composition of the Canadian 5Zjm commercial fisheries haddock catch in 1998 compared to the average for three periods which represent different stages in the Georges Bank fishery.

Figure 8. Catch rates for haddock from the Canadian commercial fishery in 5Zjm. (LL = longline, OT = otter trawl, TC = tonnage class).

Figure 9. Stratification scheme used for NMFS surveys. The 5Zjm management area is indicated by shading.

Figure 10. Stratification scheme used for the DFO survey. The 5Zjm management area is indicated by shading.

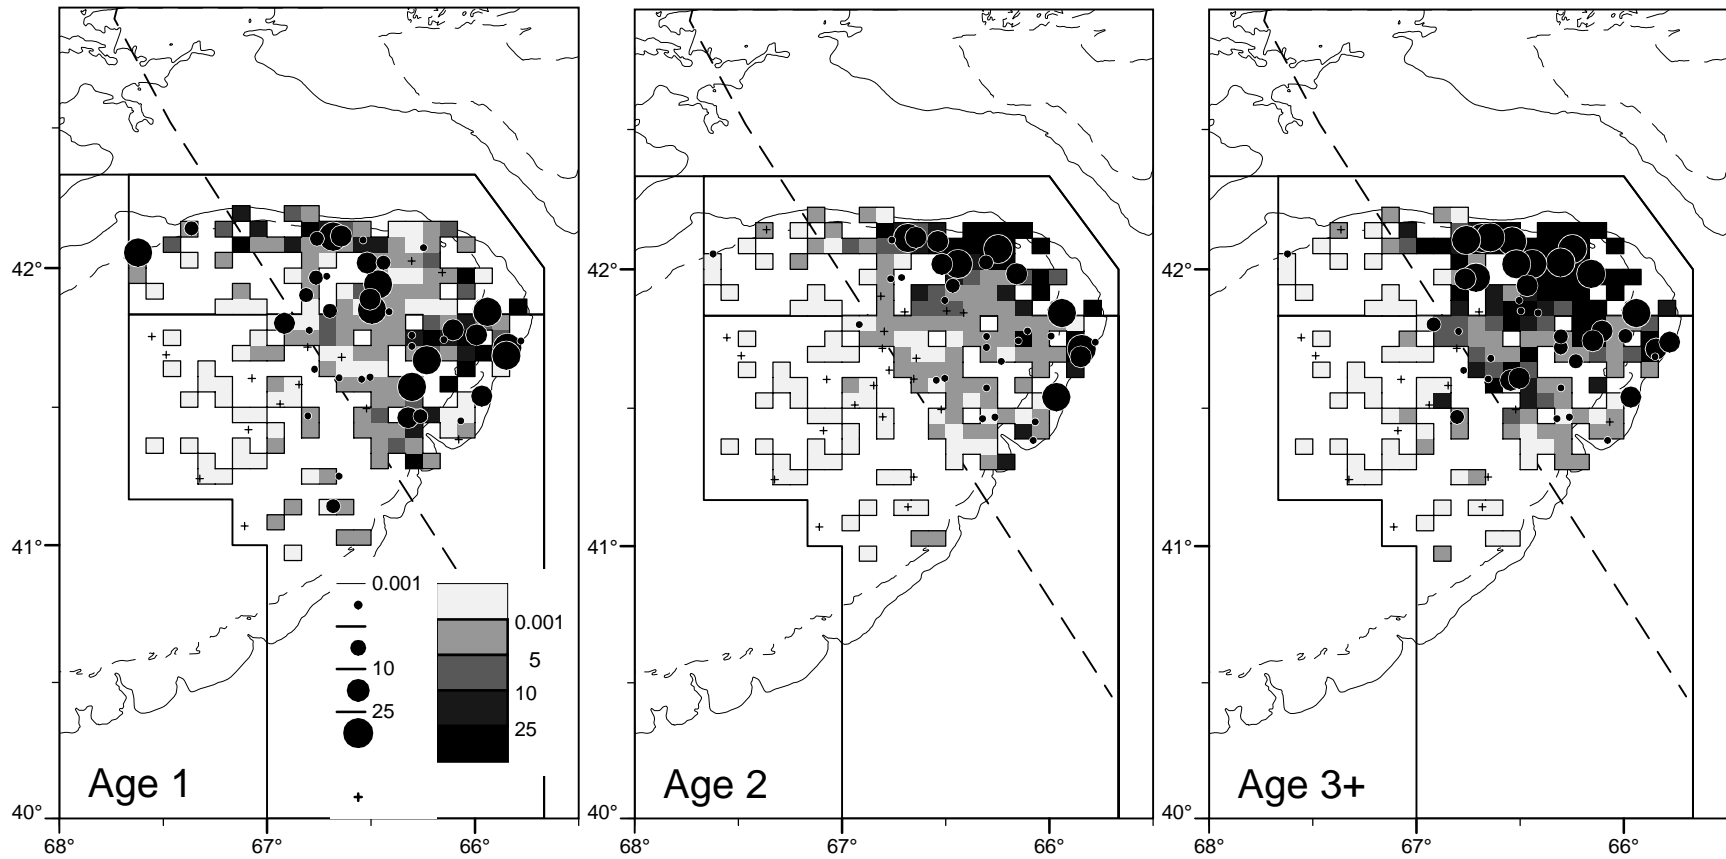

Figure 11. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **DFO spring** survey. The squares are shaded relative to the average catch for 1994 to 1998. The expanding symbols represent the 1999 survey catches.

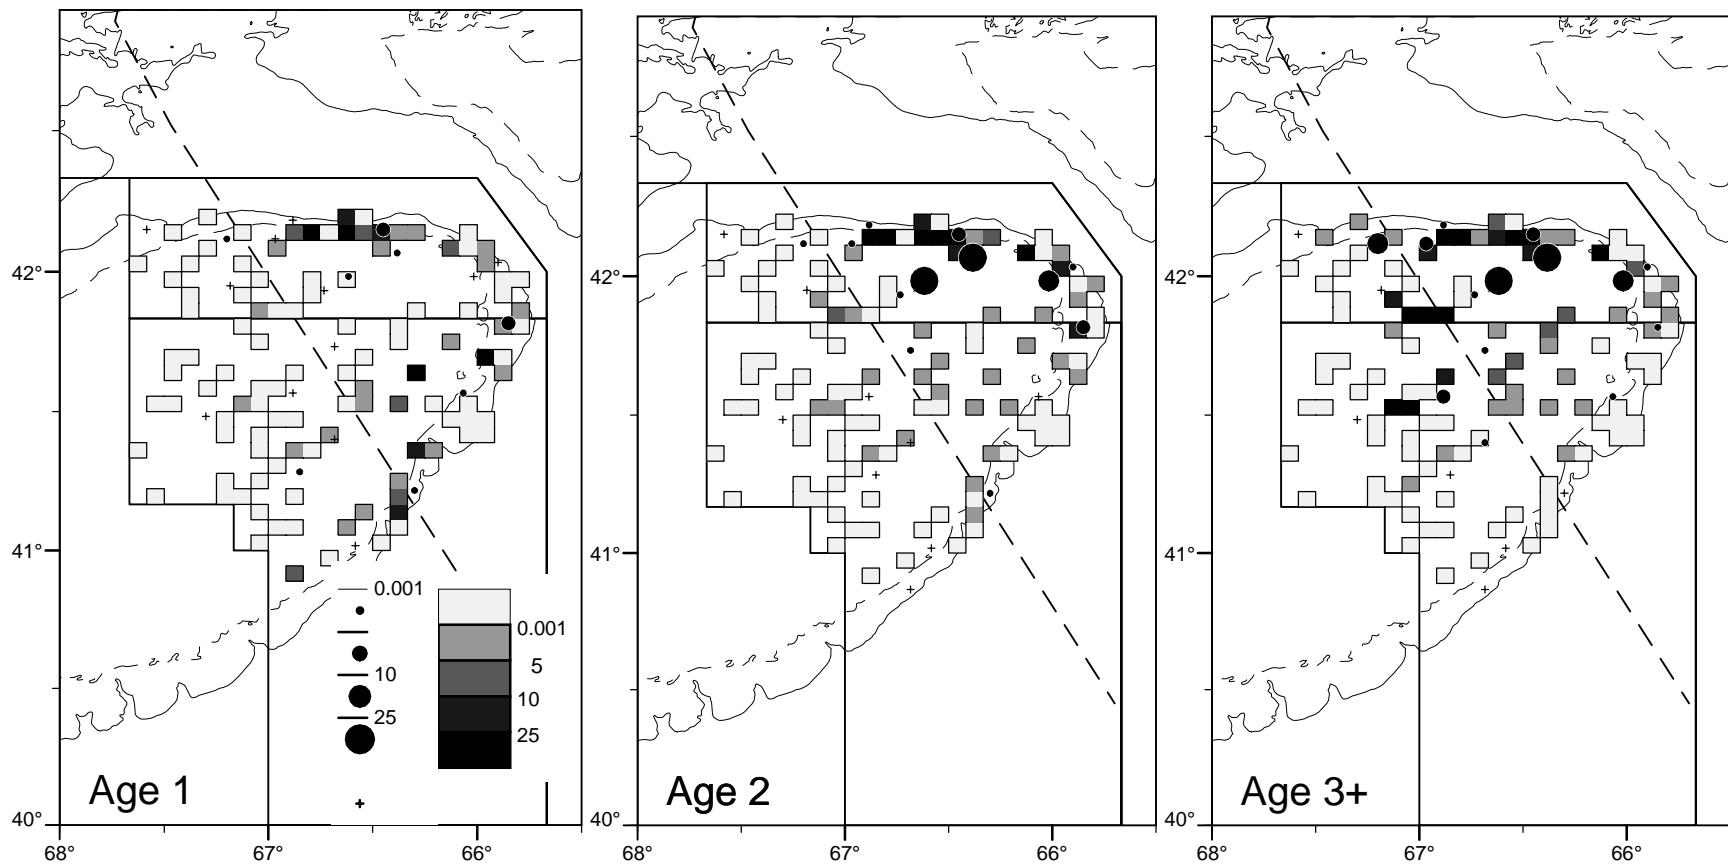

Figure 12. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **NMFS spring** survey. The squares are shaded relative to the average catch for 1993 to 1997. The expanding symbols represent the 1998 survey catches.

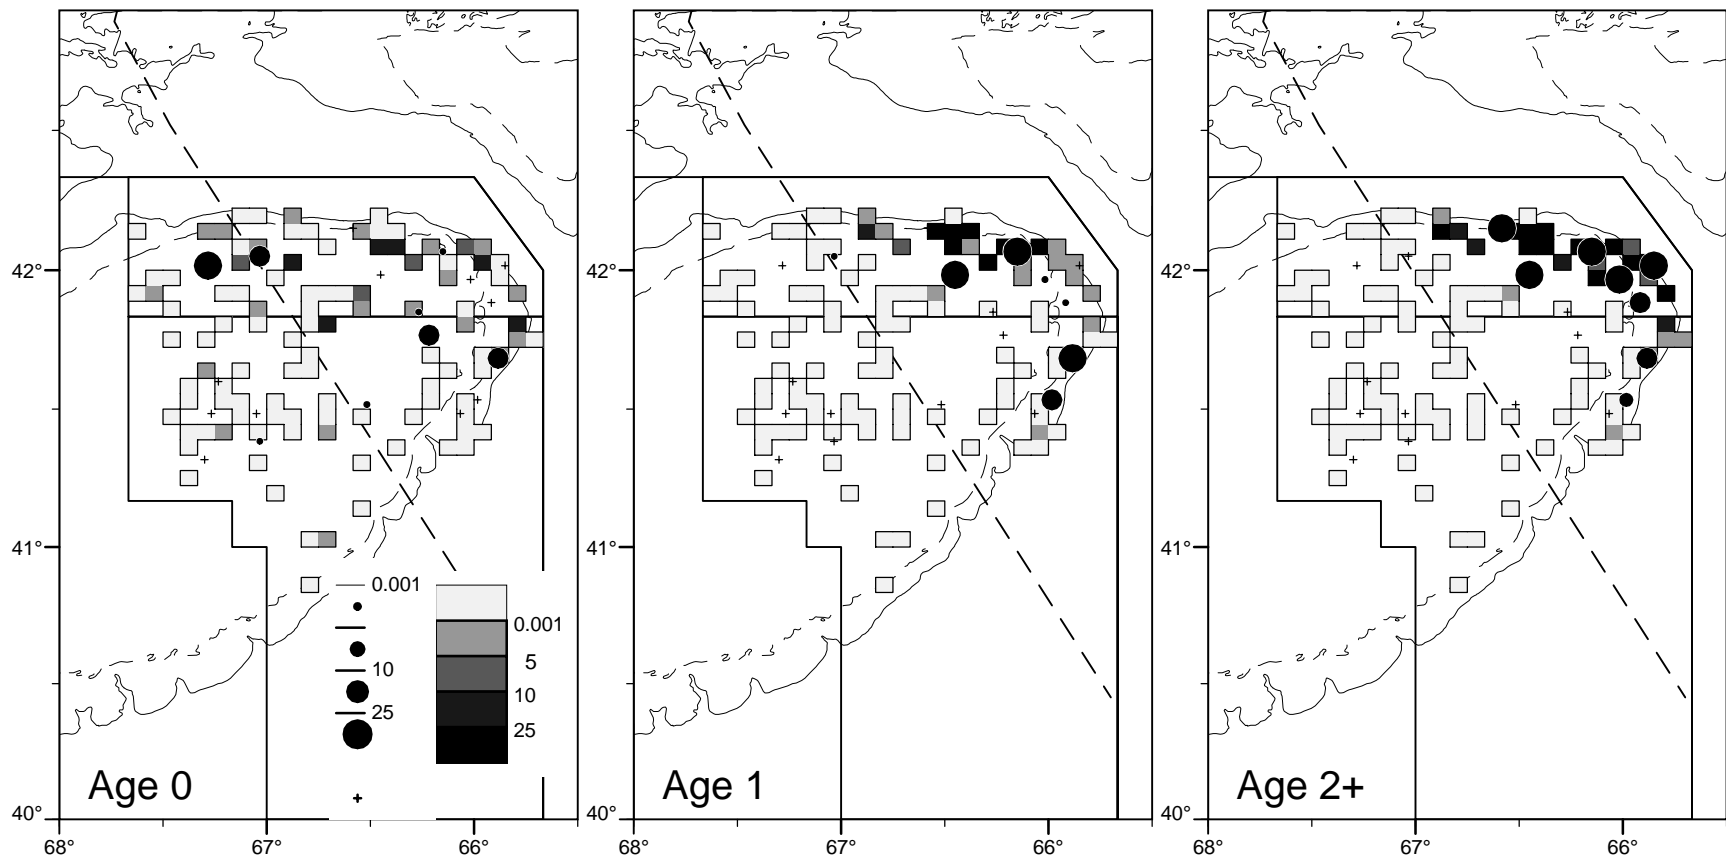

Figure 13. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **NMFS fall** survey. The squares are shaded relative to the average catch for 1993 to 1997. The expanding symbols represent the 1998 survey catches.

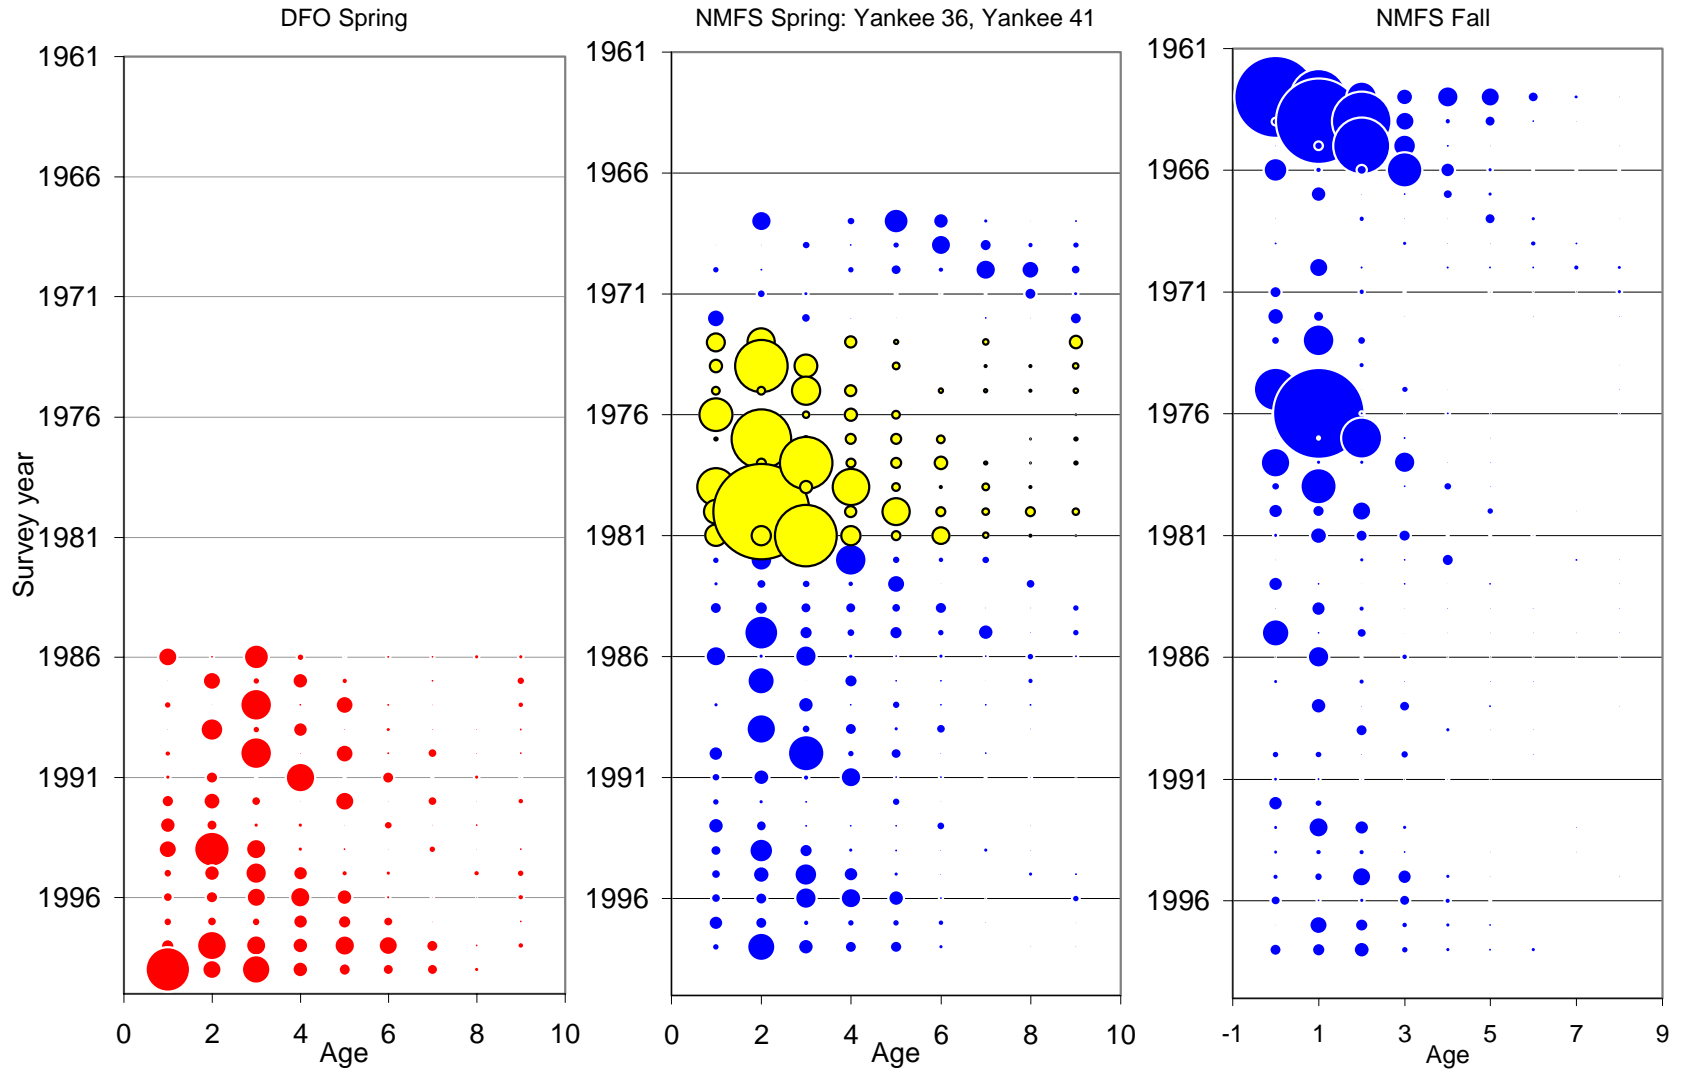

Figure 14. Estimated abundance at age (numbers in 000's) of haddock for the DFO and NMFS spring surveys and the NMFS fall survey. Bubble area is proportional to magnitude (see Tables 12-14). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81, a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 15. Biomass for ages 3-8 from the NMFS and DFO research surveys (adjusted by calibration constants) for haddock in unit areas 5Zjm. Solid circle = NMFS fall (October/November); Open circle = NMFS spring (March/April); Square = DFO spring (February/March).

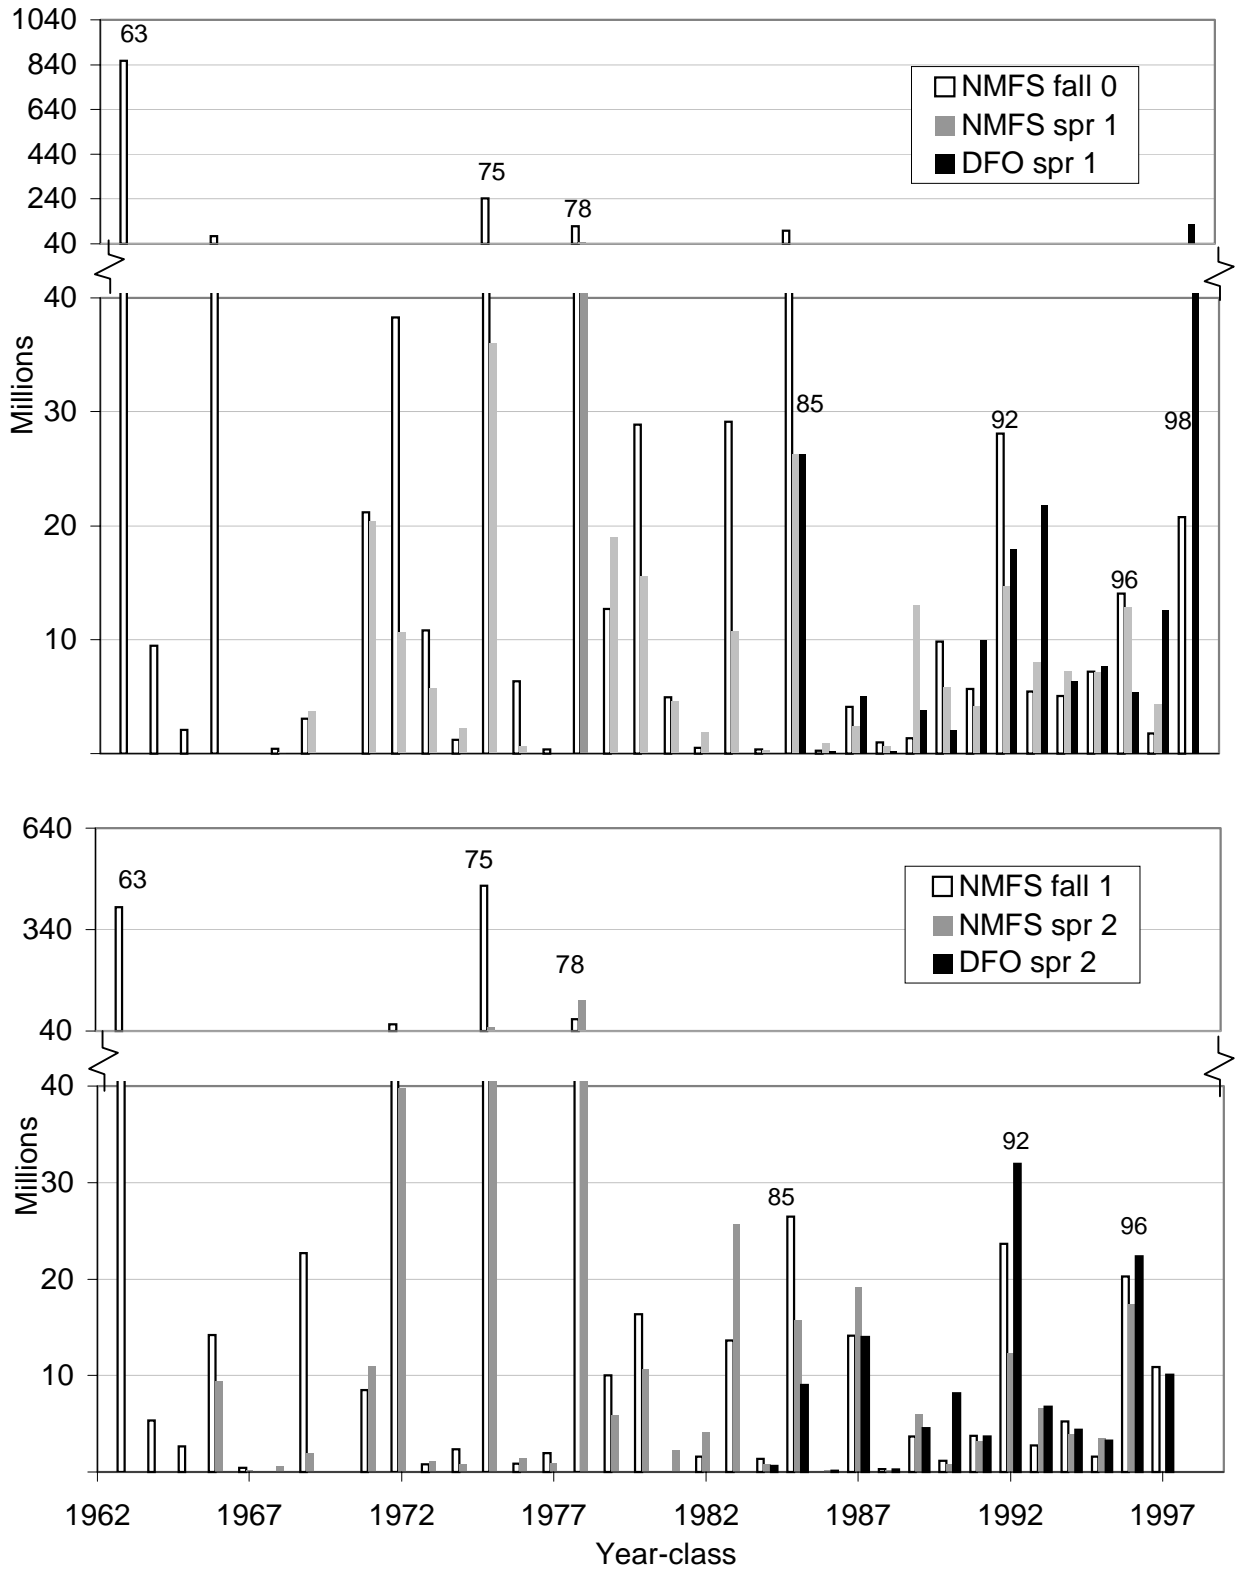

Figure 16. Year-class abundance for ages 0 and 1 from the NMFS fall and ages 1 and 2 from the NMFS and DFO spring research surveys (adjusted by calibration constants) for haddock in unit areas 5Zjm.

Figure 17. Weight at age for haddock in unit areas 5Zjm derived from the DFO spring surveys.

Figure 18. Weight at age for haddock in unit areas 5Zjm derived from the commercial fisheries.

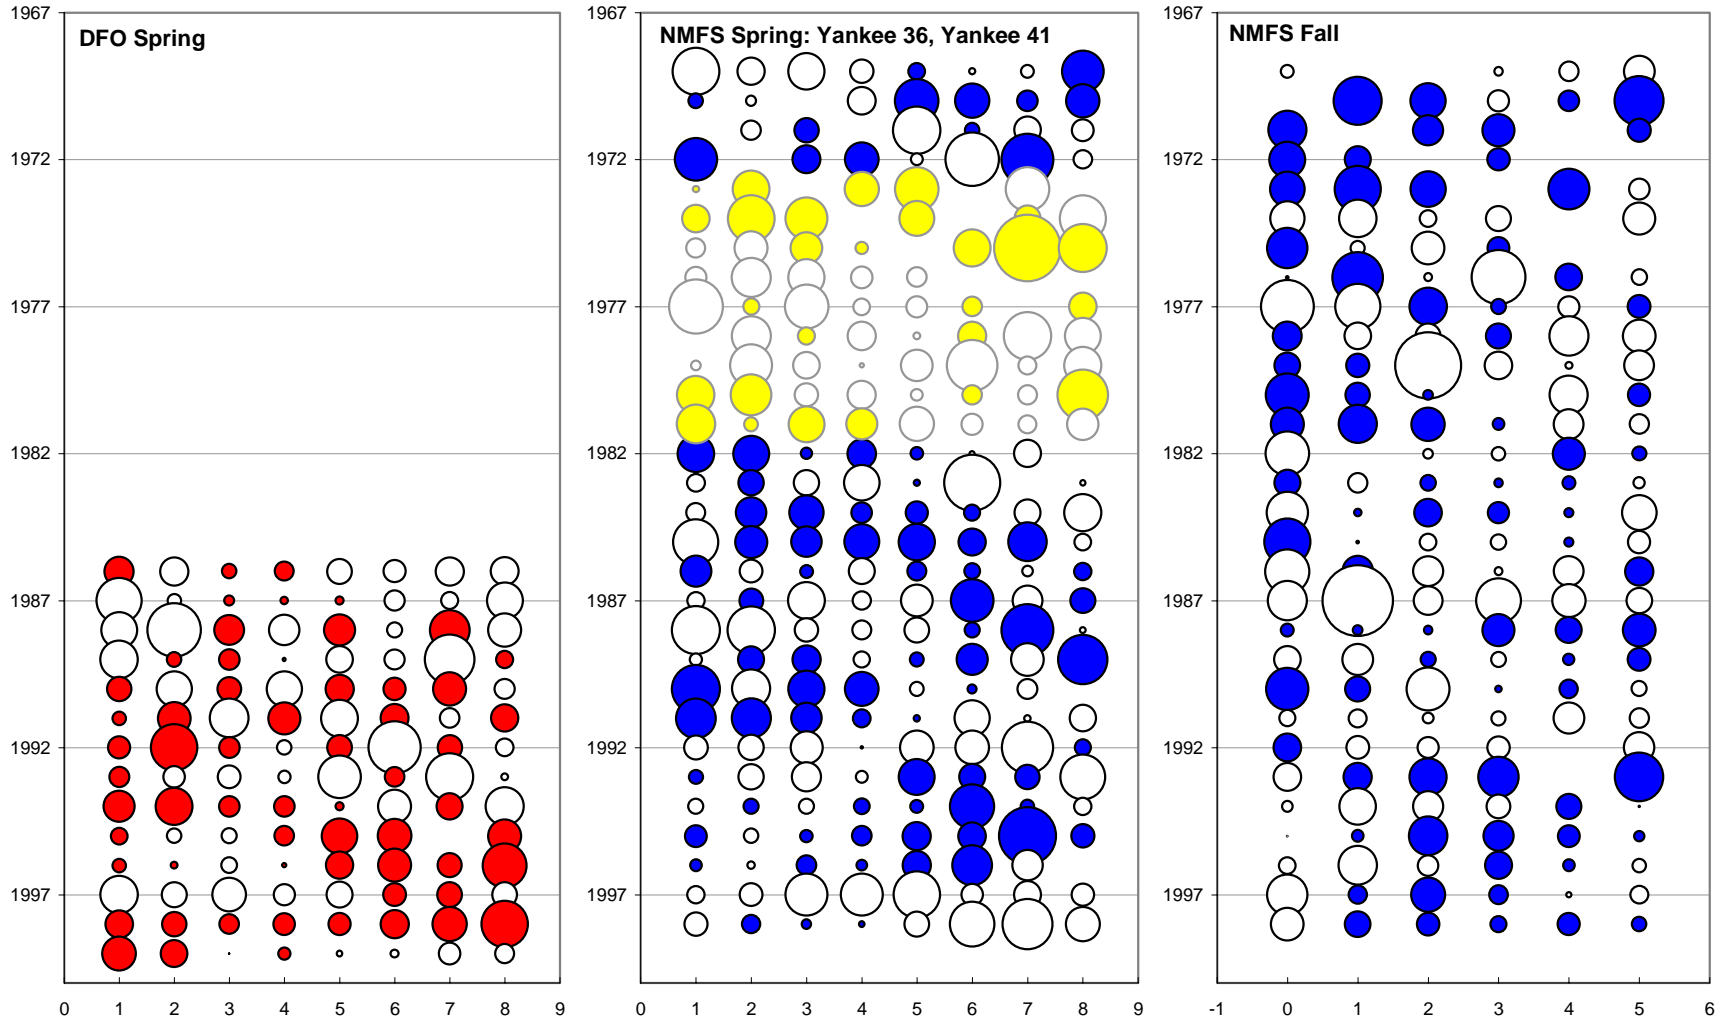

Figure 19. Residuals by year and age group for each research survey index. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude.

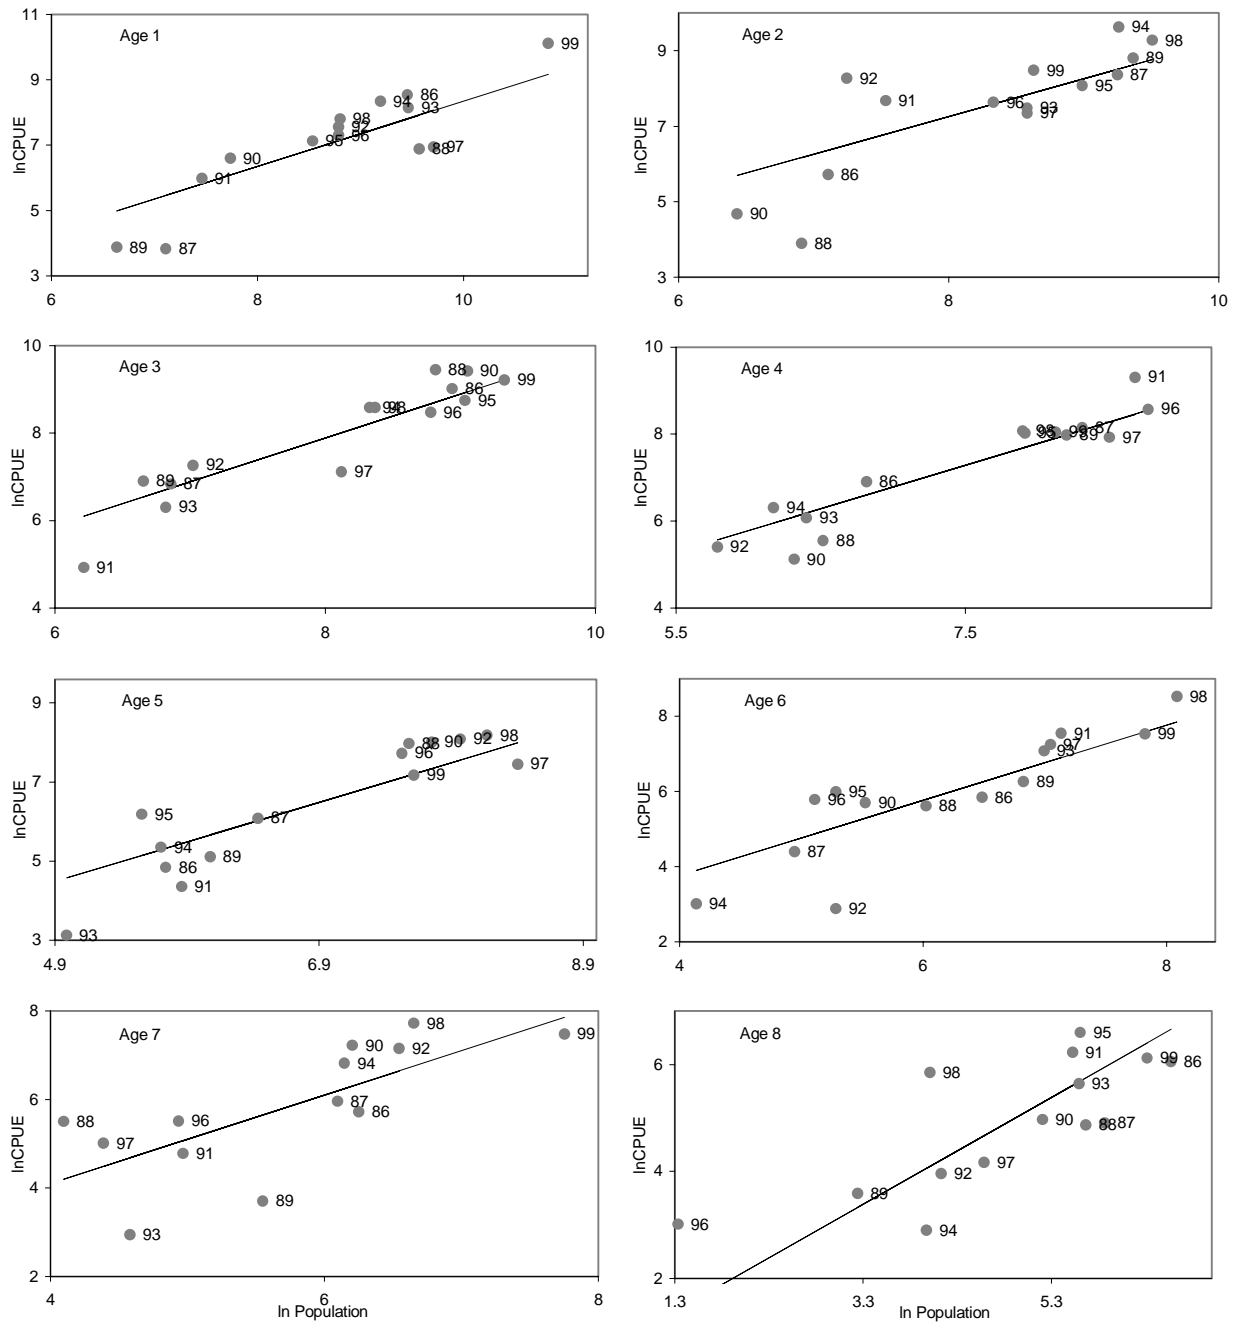

Figure 20. Age by age plots of the observed and predicted ln abundance index versus ln population numbers for haddock in unit areas 5Zj and 5Zm from the **DFO spring** survey.

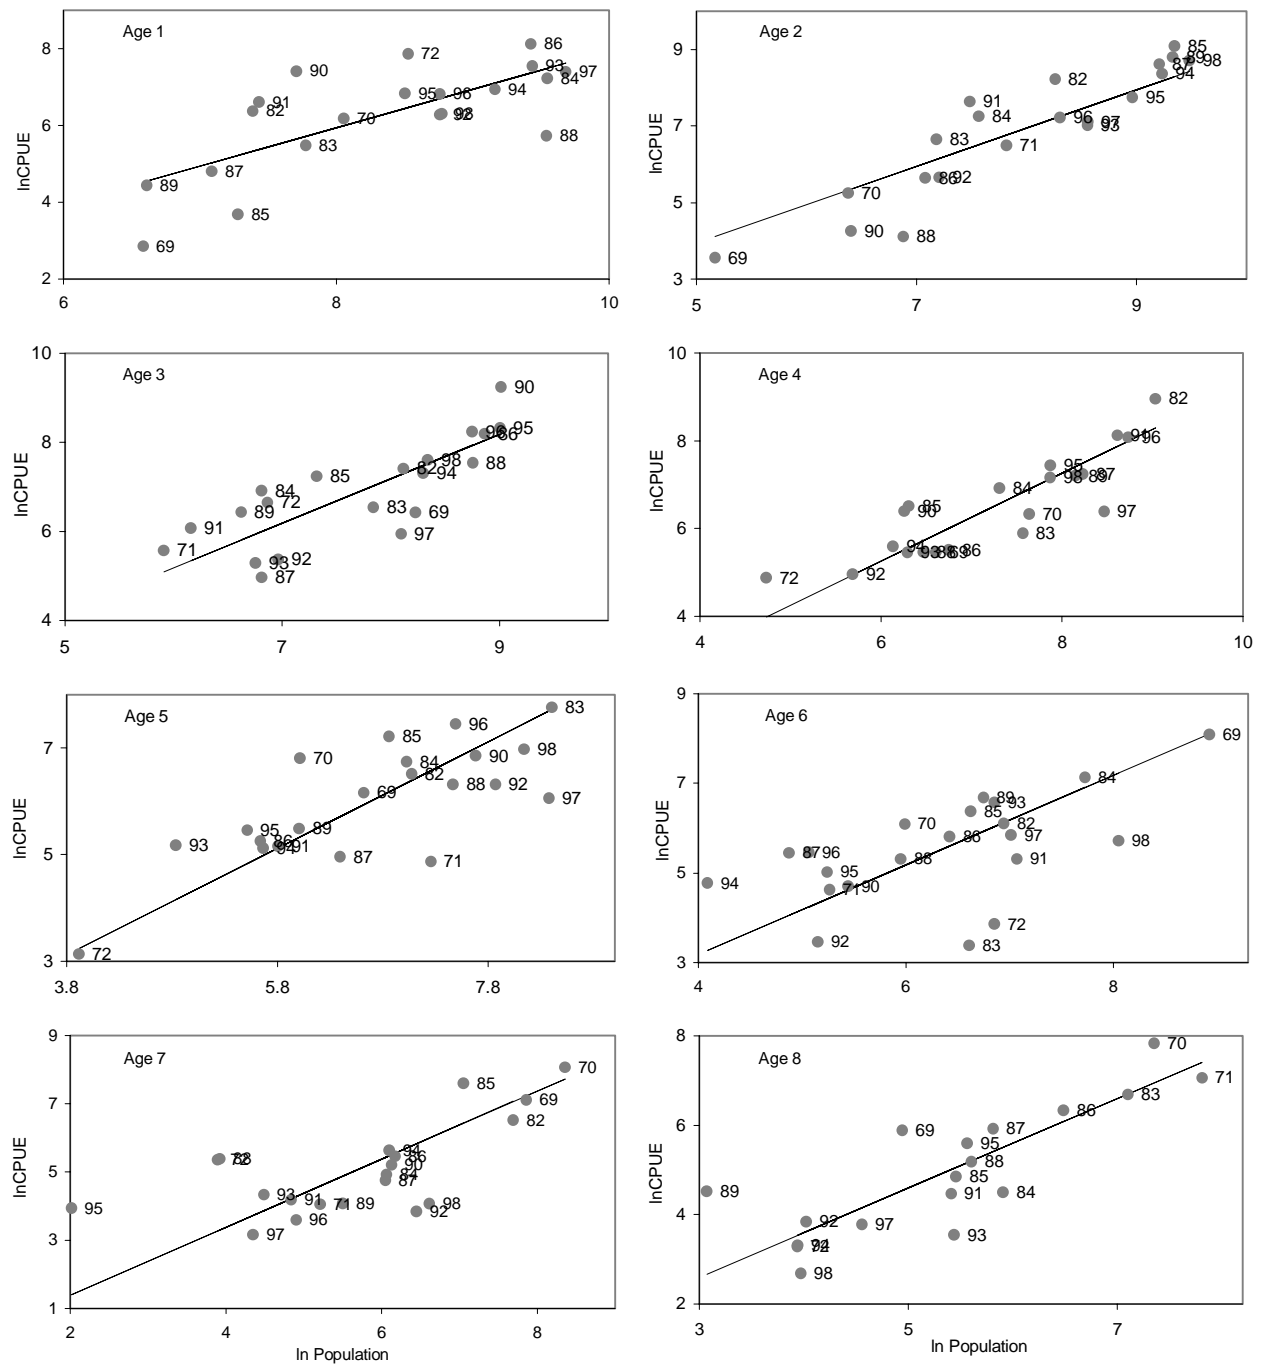

Figure 21. Age by age plots of the observed and predicted ln abundance index versus ln population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS spring survey with a Yankee 36 net.

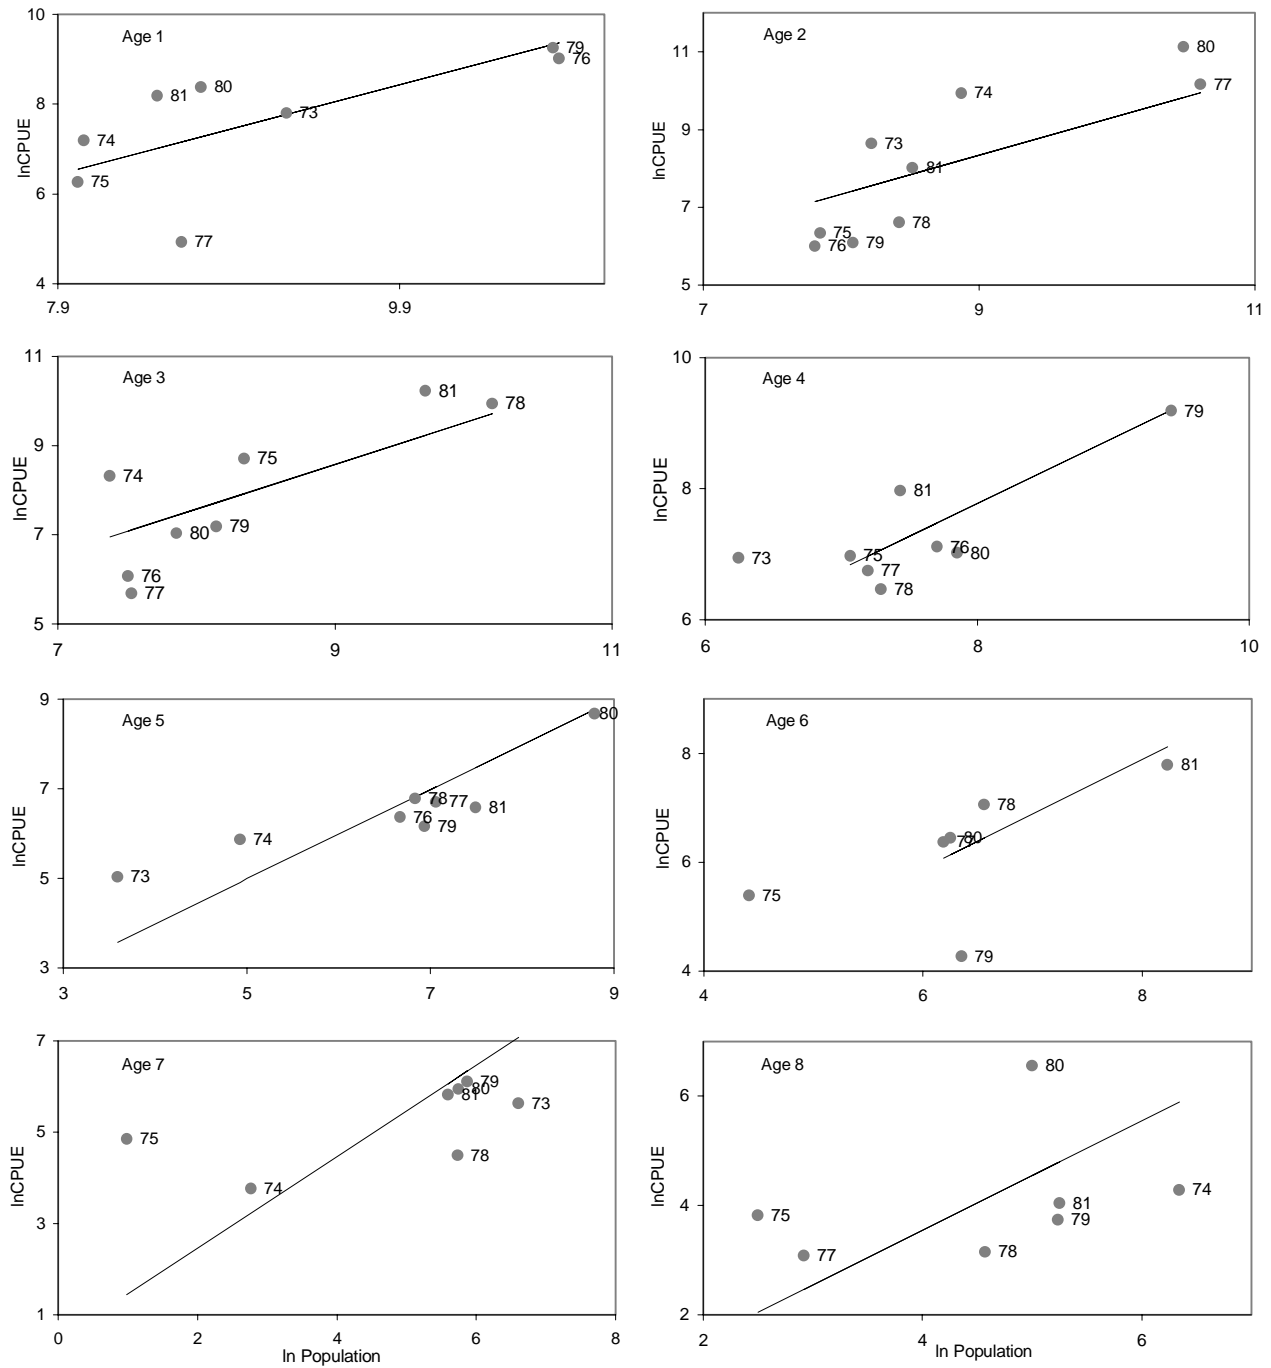

Figure 22. Age by age plots of the observed and predicted ln abundance index versus ln population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS spring survey with a Yankee 41 net.

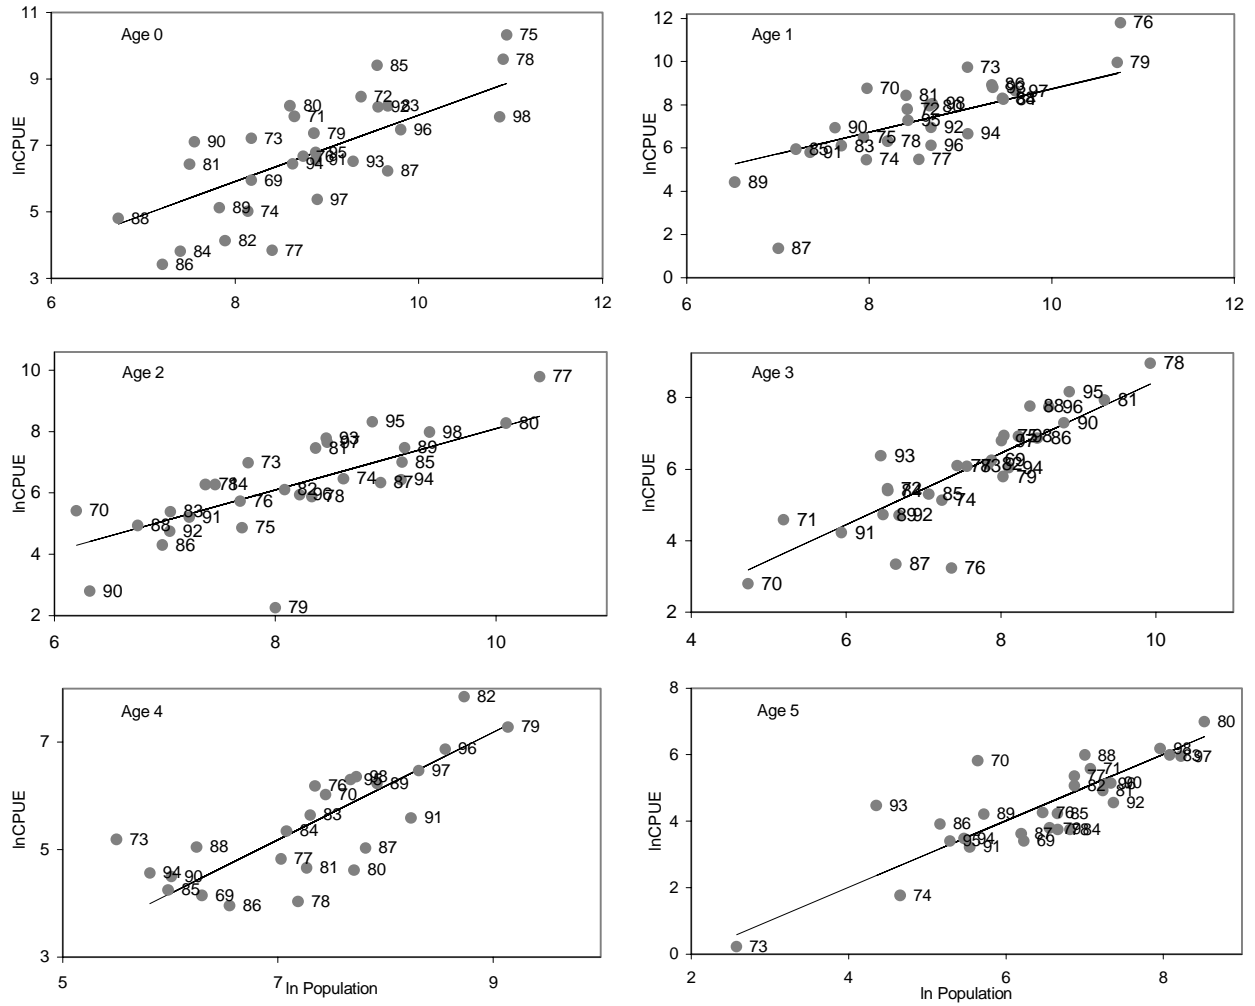

Figure 23. Age by age plots of the observed and predicted  $\ln$  abundance index versus  $\ln$  population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS fall survey.

Figure 24. Successive estimates of year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

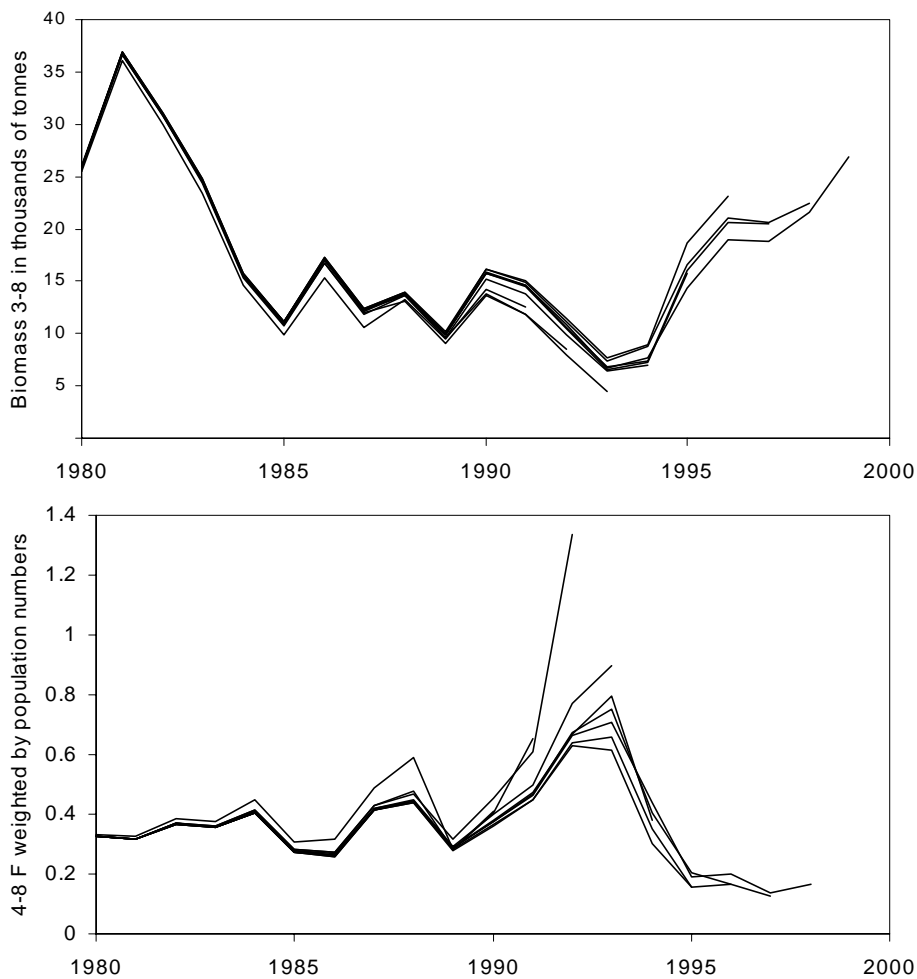

Figure 25. Retrospective estimates of biomass and fishing mortality did not display any persistent trends for over or under estimation as successive years of data were excluded in the assessment.

Figure 26. Beginning of year biomass for haddock in unit areas 5Zjm.

Figure 27. Number of age 1 recruits for haddock in unit areas 5Zjm.

Figure 28. Exploitation rate for haddock ages 4 to 8 in unit areas 5Zjm.

Figure 29. Decay of the 1992 5Zjm haddock year-class versus the 1983, 1975 and 1978 as they progress through the fishery.

Figure 30. Comparison of age composition and absolute abundance of the 5Zjm haddock population in 1998 to earlier periods.

Figure 31. Amount of productivity attributable to growth of ages 2 to 8 5Zjm haddock and the amount contributed by recruitment of age 2 haddock.

Figure 32. Surplus production of 5Zjm haddock available to the commercial fishery compared to amount actually harvested.

Figure 33. Historic catch and biomass of haddock in 5Zjm compared to recent catches and biomass.

Figure 34. Relationship between mature (3-8) 5Zjm haddock biomass and recruits at age 1 from 1931 to 1955 and 1969 to 1997.

Figure 35. Ratio of recruits (numbers at age 1) per spawning biomass (kg) suggests that present survivorship appears comparable to that of the 1930s to 1950s.

Figure 36. Expected exploitation rate in 1999 and expected change in biomass from 1999 to 2000 for 5Zjm haddock at various quotas.

Figure 37. Probability of fishing mortality exceeding the  $F_{0.1}$  ( $=0.25$ ) reference level and of the 2000 biomass being less than the 1999 biomass by 0%, 10% and 20% for 5Zjm haddock at various quotas.

## Appendix A.

Inter and intra-reader agreement tests for L. Van Eeckhaute, the DFO reader, and N. Munroe, the NMFS reader.

DFO 1998 Spring Survey (N773)

	1	2	3	4	5	6	7	8	9	11	13	14	Total
1	22												22
2		23											23
3			9										9
4				3									3
5					7	1							8
6						12							12
7							7	1					8
8							1	4					5
9									3				3
10										1			1
11										4			4
13											1	1	2
Omitted						1							1
Total	22	23	9	3	7	14	8	5	3	5	1	1	101

Percent agreement =  $95 \div 100 = 95\%$  (1 omitted, not used in calculation)

Figure A1. Intra-reader ageing agreement matrix for L. Van Eeckhaute for ageing material from the 1998 DFO spring survey.

DFO 1998 Spring Survey (N773)													
L. Van Eeckhaute	N. Munroe												
	1	2	3	4	5	6	7	8	9	10	11	12	Total
1	11												11
2		13		1									14
3			4										4
5					3								3
6						1	3						4
7							5						5
8							1	1	1				3
9										1			1
10										1			1
11											1	1	2
13												1	1
Omitted							1						1
Total	11	13	4	1	3	1	10	1	1	2	1	2	50

Percent agreement =  $40 \div 49 = 82\%$  (1 omitted, not used in calculation)

Figure A2. Ageing agreement matrix between N. Munroe, the NMFS reader, and L. Van Eeckhaute, the DFO reader, for ageing material from the 1998 DFO spring survey.

NMFS 1997 Fall Survey (9706)							
L. Van Eeckhaute	N. Munroe						Total
	1	2	3	4	5	8	
1	8						8
2		15	1				16
3		2	7				9
4		1		6			7
5				1	8		9
8						1	1
Total	8	18	8	7	8	1	50
Percent agreement = $45 \div 50 = 90\%$							

Figure A3. Ageing agreement matrix for N. Munroe, the NMFS reader, and L. Van Eeckhaute, the DFO reader, for ageing material from the 1997 NMFS fall survey.
