<sup>1</sup> This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

<sup>1</sup> La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

## **Abstract**

Combined Canada/USA landings of yellowtail flounder on Georges Bank have been increasing over the past four years, and population biomass has been increasing since 1995. Other measures of stock abundance, such as fishery catch rates and survey size composition, support the view that the resource is recovering. Results from surplus production analyses suggest that total population biomass at the beginning of 1999 is about  $\frac{3}{4}$  of the level that can produce maximum sustainable yield. Exploitation rates have been low during the past three years. Recent recruitment is improved relative to the 1980s, and the 1997 year-class appears to be the strongest since 1980. With combined Canada/USA catches of 3100 t in 1999 (equivalent to total catches in 1998), there is a low risk of exceeding  $F_{0,1}$ , and a high probability that the population biomass will continue to increase. A major source of uncertainty in the assessment is the size of the 1997 year-class. That year-class is expected to make up about 42% of the population biomass at the beginning of 2000, and comprise about 13% of the fishery catch in 1999.

## **Résumé**

Les débarquements canado-américains combinés de limande à queue jaune du banc Georges sont en hausse depuis quatre ans, et la biomasse de la population augmente depuis 1995. D'autres mesures de l'abondance du stock, comme les taux de capture de la pêche commerciale et la composition par taille dans les relevés, viennent confirmer que la ressource est en voie de rétablissement. Les résultats des analyses de la production excédentaire permettent de penser que la biomasse totale de la population se trouve, au début de 1999, à environ  $\frac{3}{4}$  du niveau qui doit permettre d'atteindre un rendement maximal soutenu. Les taux d'exploitation sont faibles depuis trois ans. Le recrutement s'est amélioré par rapport aux années 80, et la classe de 1997 semble la plus forte depuis 1980. Avec des prises combinées canado-américaines de 3 100 t en 1999 (volume équivalent au total des prises de 1998), il existe un risque faible de dépasser  $F_{0,1}$ , et une forte probabilité de voir la biomasse de la population continuer à augmenter. La source principale d'incertitude est l'évaluation de la taille de la classe 1997 ; on prévoit que cette classe d'âge devrait représenter environ 42 % de la biomasse de la population au début de l'an 2000, et constituer environ 13 % des prises commerciales en 1999.

## Introduction

Georges Bank yellowtail flounder are a transboundary resource. This paper updates the last major stock assessment of yellowtail flounder on Georges Bank which was completed jointly by Canada and the USA (Neilson and Cadrin, 1998). Similar methods are used in the current assessment, with updated catch information and indices of abundance from both countries.

Yellowtail flounder (*Limanda ferruginea*) range from Labrador to Chesapeake Bay and are typically caught at depths between 37 and 73 m, and a major concentration occurs on Georges Bank from the NE peak to the east of the Great South Channel. Yellowtail flounder appear to be relatively sedentary, although seasonal movements have been reported (Royce et al. 1959). Spawning occurs during spring and summer, peaking in May. Larvae are pelagic for a month or more, then develop demersal form and settle to benthic habitats. Growth is sexually dimorphic, with females growing at a faster rate than males (Moseley 1986). Based on tagging investigations (Royce et al. 1959; Lux 1963), the management unit is considered to include Georges Bank encompassing statistical areas 5Zj, 5Zm, 5Zn and 5Zh (Fig. 1). Thus, the management unit is transboundary in nature. Both the USA and Canada employ the same convention for the management unit.

### *The Fisheries*

Landings of Georges Bank yellowtail flounder from 1935 to the present are shown in Fig. 2 (top panel). Landings, which have been predominantly taken by the U.S. fleet, gradually increased to 7,300 mt in 1949, decreased in the early 1950s to 1,600 mt in 1956, and increased again in the late 1950s. Annual catches including discards are available since 1963 (see Fig. 2, bottom panel), and have averaged 16,300 mt during 1962-1976, with some taken by distant water fleets. No foreign catches of yellowtail have occurred since 1975. In every year since 1985, catches have been 5,000 mt or less.

#### USA

The principle fishing gear used in the USA fishery to catch yellowtail flounder is the otter trawl, but scallop dredges and sink gillnets contribute some landings. In recent years, otter trawls caught greater than 95% of total landings from the Georges Bank stock, dredges caught 2-5% of annual totals, and gillnet landings were less than 0.1%. Current levels of recreational and foreign fishing are negligible. Discarding of small yellowtail is an important source of mortality due to intense fishing pressure, discrepancies between minimum size limits and gear selectivity, and recently imposed trip limits for the scallop dredge fishery. U.S. trawlers that land yellowtail flounder generally target multiple species on the 'Southwest Part' of the Bank, and on the northern edge just east of the closed area adjacent to the international boundary. Methods of estimating U.S. discards described in NEFSC (1997) indicate that 1998 discards were approximately 114 mt.

## Canada

The Canadian fishery for yellowtail flounder is directed and began in 1993. Prior to 1993, Canadian landings were small, typically less than 100 t (Table 1, Fig. 2). Peak landings of 1,328 t of yellowtail occurred in 1994, when the fishery was unrestricted. After a TAC of 400 t was established, yellowtail landings dropped to 397 t in 1995. In 1998, landings of yellowtail flounder were 1,175 t against a quota of 1,200 t (Table 1).

The majority of Canadian landings of yellowtail flounder are made by otter trawl, from vessels less than 65 ft, Tonnage Classes (TC) 2 and 3. The fishery takes place from June to December, with peak months for fishing activity occurring from July to October in 1998.

The Canadian yellowtail directed fishing activity was concentrated in the southern half of the Canadian fishing zone, in the portion of 5Zm referred to as the "Yellowtail Hole". The distribution of fishing activity over the past four years is shown on Fig. 3. The fishery distribution in 1998 was comparable to that observed in the previous three years.

Flatfish landed as "unspecified" in the Canadian fishery have been significant in previous years, and generally consist of yellowtail on Georges Bank. The unspecified flounder problem has become less significant recently, due to improved monitoring of the landings. In 1998, only 16 t of unspecified flounder were landed from 5Zm, and all were assumed to be yellowtail flounder. Total unspecified flounder from 5Zjm were 32 t.

In previous years, there have been some landings of yellowtail flounder in the Canadian scallop fishery on Georges Bank. Management measures established in 1996 prohibit the landing of yellowtail flounder by this fleet, and no records of discarded quantities are available for 1997. This represents a source of mortality for this resource that is of unknown magnitude, and efforts are required to quantify discarded catches. In 1996, at-sea observer records estimated the amount of discarded yellowtail flounder as 11 t.

### *Age and Length Composition*

Sampling information for 1998 is summarized in Table 2. In general, sampling of the fishery by both countries continues to be inadequate. For the United States, no sampling information is available to characterize the fishery during the fourth quarter of 1998. Canada has more length measurements available through that period, but no age determinations have been made (Canada collects age determination material, but the age determination program is not yet operational). The low number of age determinations available has once again hampered the development of reliable age length keys, to an even greater extent. Only 293 age determinations were available, compared with 579 in the previous assessment.

However, the suspected problem in species misidentification in the Canadian sea samples in 1997 did not recur in 1998. Thus, that source of information was used to characterize the size composition of the Canadian fishery, along with length samples from the DFO port sampling program. The comparability of the length-frequency information from the two sources supports the view that culling on the basis of length was not a major concern in the 1998 fishery (Fig. 4).

The combined catch at age and weight at age information for both countries is shown in Tables 3 and 4, respectively. Ages 3 and 4 dominate in both the Canadian and USA fisheries (Fig. 5), and there is limited indication of year-class tracking (Fig. 6). There has been no recent trend in the weight at age data (Fig. 7).

The USA fishery caught smaller fish in 1998 than those landed in the Canadian fishery (Fig. 8). The length-frequency distributions of the USA catch exhibited a steeply ascending left-hand limb compared with the Canadian distributions, that may reflect size-related discarding or differential distribution by size within the management unit. The Canadian fishery is also typified by an increasing average size of the landings from 1994 to 1998 (Fig. 9).

### **Abundance Indices**

#### *Commercial Fishery Catch Rates*

Catch (t) and effort (h) for less than 65 ft Canadian otter trawlers fishing for yellowtail flounder in 1993-98 were summarized on a trip basis. Initial examination of the trip records showed a large proportion of trips with very small amounts of yellowtail in the total catch. These trips were not considered to be representative of yellowtail directed effort, and therefore only trips with reported landings from 5Zm of more than 500 kg (1100 lb.) were included in the CPUE estimates. As well, only vessels with reported landings in two or more years in 1993-97 were included in the analysis.

Yellowtail landings and effort for trips were aggregated by month and year, and monthly catch rates (t/h) are shown in Fig. 10. The catch rate decreased between 1993 and 1994 but increased by a factor of over two between 1994 and 1995 and increased further in 1996 and 1997. The catch rate declined somewhat from 1997 to 1998.

Substantial gear changes occurred in the fishery between 1993 and 1994 with the introduction of 'flounder gear' which uses a small diameter footgear. However, fishing practices have been relatively constant since then. Fishermen have indicated that while the increasing trend of catch rates from 1994 to 1997 reflect increased abundance, they also acknowledged that there was a learning factor associated with this relatively young fishery. While catch rates may prove to be useful as an index of abundance for this resource, the time series is too short to be included directly in the assessment at present.

## *Research Vessel Surveys*

Bottom trawl surveys are conducted annually on Georges Bank by the Canadian Department of Fisheries and Oceans (DFO) in February and by the USA NMFS in March and October - November. Both agencies use a stratified random design, though different strata boundaries are defined (Fig. 11). USA spring and autumn bottom trawl survey catches (strata 13-21), USA scallop survey catches, and Canadian bottom trawl survey catches (strata 5Z1-5Z4, Fig. 11) were used to estimate relative stock biomass and relative abundance at age for Georges Bank yellowtail. Standardization coefficients, which compensate for survey door, vessel, and net changes in USA groundfish surveys (1.22 for old doors, 0.85 for the Delaware II, and 1.76 for the 'Yankee 41' net; Rago et al. 1994) were applied to the catch of each tow.

The DFO spring survey series has followed an increasing trend since 1995 and the 1999 value is the highest in the series. The NMFS spring series is longer, and tracks the DFO series well during the years of overlap (Tables 5 and 6, Fig. 12). The NMFS fall series also increases in 1995, but the recent values are still low compared with the early years of this survey, which is the longest running series of the three groundfish surveys (Table 7, Fig. 13). The NMFS scallop survey is used as an index of abundance for age 1. The index has been following an increasing trend since 1990. The most recent value is the second highest in the series (Table 8, Fig. 14).

For all three groundfish surveys, the distribution of catches in the most recent survey is comparable with those distributions observed in the previous five years, on the average (see Figs. 15, 16 and 17 for the DFO spring, NMFS spring and fall surveys, respectively).

The length composition of the catch of yellowtail flounder taken in the DFO surveys has shown a trend of increasing size from 1995 to 1998 (Fig. 18). This is consistent with the increase in average length of the catch of yellowtail flounder.

Age-structured indices from the survey do not always track cohort well (Fig. 19). Also, there are some indications of year-effects in the series, as indicated in the DFO spring surveys.

## **Estimation of Stock Parameters**

### *Calibration of VPA*

The Virtual Population Analysis (VPA) used annual catch at age,  $C_{a,t}$ , for ages  $a = 1$  to  $5+$ , and time  $t = 1973$  to  $1998$ , where  $t$  represents the beginning of the time interval during which the catch was taken. The VPA was calibrated to bottom trawl and scallop survey abundance indices,  $I_{s,a,t}$ , for

$s = \text{DFO spring, ages } a = 1 \text{ to } 5+, \text{ time } t = 1987 \text{ to } 1999$

$s = \text{NMFS spring (Yankee 36), ages } a = 1 \text{ to } 5+, \text{ time } t = 1982 \text{ to } 1998$

$s = \text{NMFS spring (Yankee 41), ages } a = 1 \text{ to } 5+, \text{ time } t = 1973 \text{ to } 1981$

$s$  = NMFS fall, ages  $a$  = 1 to 5+, time  $t$  = 1973.5 to 1998.5

$s$  = NMFS scallop, age  $a$  = 1, time  $t$  = 1982 to 1998

The NMFS spring age-length key is used with the DFO spring survey to derive survey abundance at age. As a corresponding age-length key for the DFO spring 1999 survey was not available, an iterative technique using the NMFS spring 1998 length at age information was applied (Kimura and Chikuni 1987). The NMFS scallop survey captures young fish and information for age 1 is used, but older yellowtail appear less available to this survey. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. Data were aggregated for ages 5 and older to mitigate against frequent zero observations. The fishing mortality rate for the 5 plus group was calculated according to the "alpha" method (Restrepo and Legault 1994).

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the sequential population analysis with the research survey abundance trend results. The model formulation employed assumed that the random error in the catch at age was negligible. The errors in the abundance indices were assumed independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate, M, was assumed constant and equal to 0.2. The fishing mortality rates for age groups 4 and 5+ were assumed equal. These model assumptions and methods were similar to those applied in the last assessment (Neilson and Cadrian 1998). Both analytical and bootstrap statistics of the estimated parameters were derived. For consistency with the risk analysis, bias adjusted VPA results were based on bootstrap statistics.

The population abundance estimates show large relative error and substantial bias at age 2 while the relative error for other ages is about 35% or less and the bias is small (Table 9). The average magnitude of residuals is large and though several large residuals can be identified, the respective observations do not appear influential and should not impact parameter estimates of current abundance (Figs. 20-25).

### *Surplus Production Analyses*

As was done last year, and recognizing the uncertainties in the age-structured information, an assessment method that does not rely upon age-structured data was also used. The ASPIC non-equilibrium surplus production methodology requires total catch and one or more indices of abundance. The indices used were DFO spring survey (1987 to 1999, lagged one year to reflect end of previous year biomass), USA spring (1968 to 1998), and USA fall (1963 to 1998). As with the VPA, the spring survey was further subdivided into two series reflecting periods when the Yankee-36 trawl (1968-1972; 1982-1997) and the Yankee-41 trawl (1973-1981) were used. Yield input includes estimates of USA discards. Following the advice of Prager (1995), the first five years of output from ASPIC are not presented, since the starting biomass in the first year is poorly estimated.

## **Stock Status**

### *Virtual Population Analysis*

The results from the standard lognormal model formulation were considered appropriate on which to base the status of the stock. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias and used to construct the history of stock status (Tables 10-11). In the absence of an unbiased point estimator with optimal statistical properties, this approach was considered preferable to using the biased point estimates. The fishery weights at age, assumed to represent mid-year weights, were used to derive beginning of year weights at age, (Table 12) and these were used to calculate beginning of year population biomass (Table 13). A value of 0.1 kg was assumed for population weight at age 1 in all years.

Population biomass (ages 1-5+) declined from about 37,000 t in 1973 to a historic low of about 7,000 t in 1991 and has subsequently increased steadily to almost 28,000 t at the beginning of 1999 (Fig. 26). The increasing trend is due principally to improved recruitment in the 1990s, but was also enhanced by increased survivorship of young yellowtail from reduced exploitation. Biomass for ages 3+ (considered to reflect mature biomass) shows a similar trend and was estimated at 17,287 t at the beginning of 1999. The strength of the 1996 year-class was estimated to be almost 30 million at age 1, the largest since the 1980 year-class (Fig. 27). Preliminary indications for the 1997 year-class indicate that it may be strong at up to almost 60 million recruits. Exploitation rate for ages 3+ has been below 20%, equivalent to  $F_{0.1} = 0.25$ , since 1996 (Fig. 28). Since 1973, exploitation rate has substantially exceeded  $F_{0.1}$  averaging about 50%. Reduced fishing mortality in recent years has resulted in increased survival of incoming year-classes.

Gains in fishable biomass may be partitioned into those associated with somatic growth of yellowtail which have previously recruited to the fishery and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as a convenient age of first recruitment to the fishery. On average, growth contributes about 60% of total production with little variation in the proportion since 1973 (Fig. 29). Surplus production is defined as the gains in fishable biomass which are in excess of the needs to offset losses from natural mortality. When the fishery yield is less than the surplus production, there is a net increase in the population biomass. Since 1995, there has been considerable production in excess of fishery removals (Fig. 29).

### *Surplus Production Analyses*

Results of the surplus production analyses are provided in Appendix A. ASPIC results indicate that a maximum sustainable yield of 13,240 t can be produced when the stock biomass is 44,360 t. The population biomass in 1999 continues to increase, and is

now estimated to be 36,210 t. Trends in biomass indicated from the surplus production analyses are very similar to those obtained from the VPA, but depart in 1998 with the VPA showing a less rapid increase (Fig. 26). The exploitation rate on total biomass in 1998 (.098) increased slightly from 1997 (.080), but is still low. Trends in exploitation rate are again qualitatively similar to those obtained from the VPA (Fig. 28).

### **Fishery Reference Points**

#### *Yield per Recruit*

The yield per recruit analysis was updated in Neilson and Cadrin (1998). We adopted those results here.

#### *Stock and Recruitment*

There is evidence of reduced recruitment at low levels of age 3+ biomass (Fig. 30). However, management actions by both countries appear to have been successful in building the population to levels where the probability of good recruitment is enhanced.

### **Outlook**

#### *Surplus Production Analyses*

As was done last year, the projection was completed assuming a biomass-weighted approximation to  $F_{0.1}$  (0.172). Biomass at the beginning of 2000 is projected to be 42,620 t. The projected 1999 yield at the  $F_{0.1}$  projected fishing mortality is 6836 t, (combined Canada and USA catch).

The projection results from the surplus production analyses imply a greater rate of population biomass increase than do the VPA projections, presented in the next section. To achieve such growth, continued successive strong year-classes are implied. Since consecutive strong year-classes are rarely observed (Fig. 27), we considered the projection results from the surplus production approach to be optimistic.

#### *Virtual Population Analysis*

Yield projections were done using the bias adjusted 1999 beginning of year population abundance estimates. The abundance of the 1998 and 1999 year-classes was assumed to be 19 million at age 1. Partial recruitment to the fishery for ages 1, 2 and 3, fishery weights at age and beginning of year population weights at age were averaged over the previous 4 years for use in the 1999 forecasts (Table 14).

Projected total Canada/USA yield at  $F_{0.1} = 0.25$  in 1999 would be about 4,300 t. If fished at  $F_{0.1}$  in 1999, the total biomass is projected to increase from 27,633 t to 30,838 t by the beginning of 2000 and an increase in 3+ beginning of year biomass of about 50%

is anticipated (Fig. 31). The 1997 year-class contributes about 13% of the expected yield in 1999, and about 42% of the total biomass.

Uncertainty about year-class abundance generates uncertainty in forecast results. This uncertainty was expressed as risk of achieving reference targets. For example, with *status quo* Canada and USA catches of 3100 t, there is a small probability of exceeding  $F_{0.1}$ , and a very high probability that total biomass will continue to increase (Fig. 32).

These uncertainty calculations do not include variations in weight at age, partial recruitment to the fishery and natural mortality, or systematic errors in data reporting and model mismatch. Therefore, overall uncertainty would be greater, but these results provide guidelines.

## CONTROL PARAMETERS USED (FROM INPUT FILE)

|                                     |           |                             |           |
|-------------------------------------|-----------|-----------------------------|-----------|
| Number of years analyzed:           | 36        | Number of bootstrap trials: | 500       |
| Number of data series:              | 4         | Lower bound on MSY:         | 5.000E+00 |
| Objective function computed:        | in EFFORT | Upper bound on MSY:         | 5.000E+01 |
| Relative conv. criterion (simplex): | 1.000E-08 | Lower bound on r:           | 1.000E-01 |
| Relative conv. criterion (restrt):  | 3.000E-08 | Upper bound on r:           | 5.000E+00 |
| Relative conv. criterion (effort):  | 1.000E-04 | Random number seed:         | 1964287   |
| Maximum F allowed in fitting:       | 5.000     | Monte Carlo search trials:  | 50000     |

## PROGRAM STATUS INFORMATION (NON-BOOTSTRAPPED ANALYSIS)

Normal convergence.

## CORRELATION AMONG INPUT SERIES EXPRESSED AS CPUE (NUMBER OF PAIRWISE OBSERVATIONS BELOW)

|   |                          | 1     | 2     | 3     | 4     |
|---|--------------------------|-------|-------|-------|-------|

## NOTES ON BOOTSTRAPPED ESTIMATES:

- The bootstrapped results shown were computed from 500 trials.
- These results are conditional on the constraints placed upon MSY and r in the input file (ASPIIC.INP).
- All bootstrapped intervals are approximate. The statistical literature recommends using at least 1000 trials for accurate 95% intervals. The 80% intervals used by ASPIIC should require fewer trials for equivalent accuracy. Using at least 500 trials is recommended.
- The bias corrections used here are based on medians. This is an accepted statistical procedure, but may estimate nonzero bias for unbiased, skewed estimators.

Trials replaced for lack of convergence:

NOTE: Printed BC confidence intervals are always approximate.  
At least 500 trials are recommended when estimating confidence intervals.

Bias-Corrected Time Plot of B-Ratio (#) with Approximate 80% Confidence Interval (^, )  
(Dashed Reference line is 1.0)

NOTE: At least one upper confidence limit was omitted from the plot.

NOTE: Estimates beginning in 2000 depend on the user projection data listed on page 1.  
Georges Bank Yellowtail --including Discards, Run 2  
Trial Projection

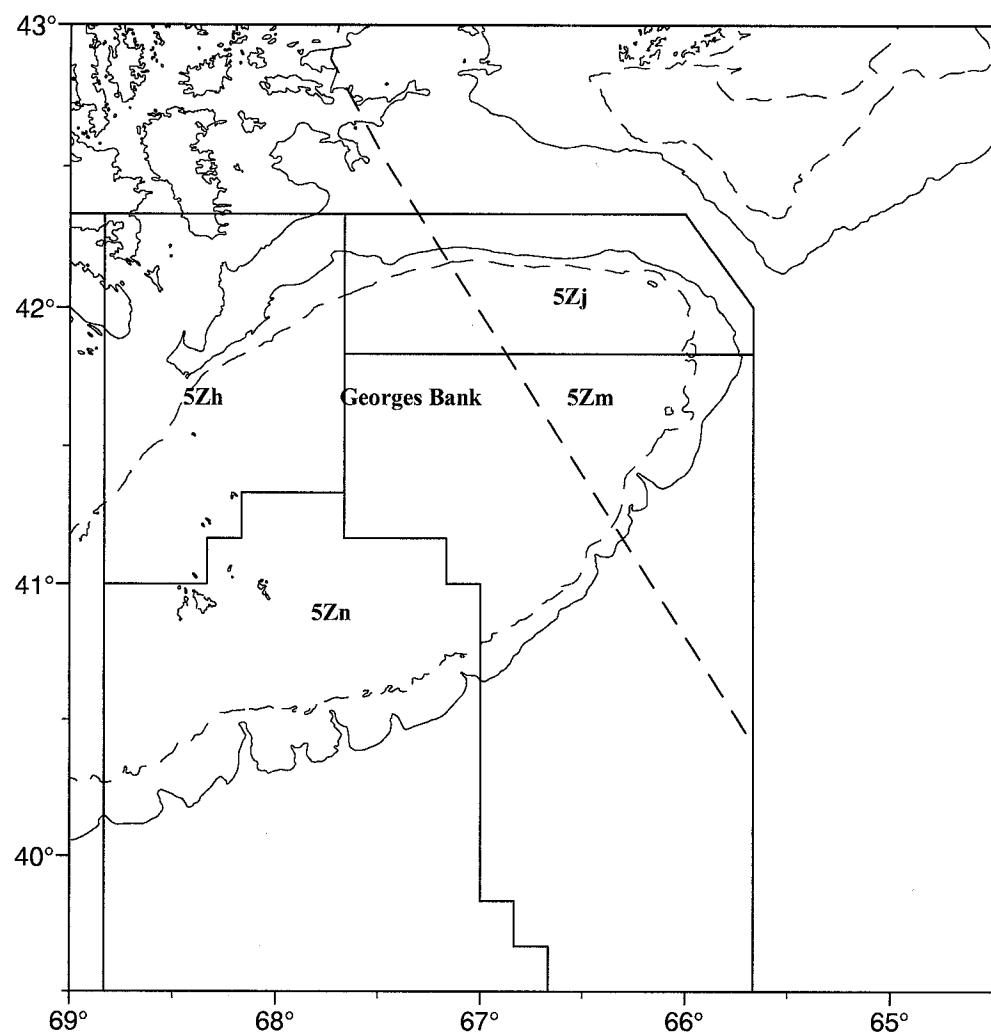

Fig. 1. Canadian fisheries statistical unit areas in NAFO Subdivision 5Ze.

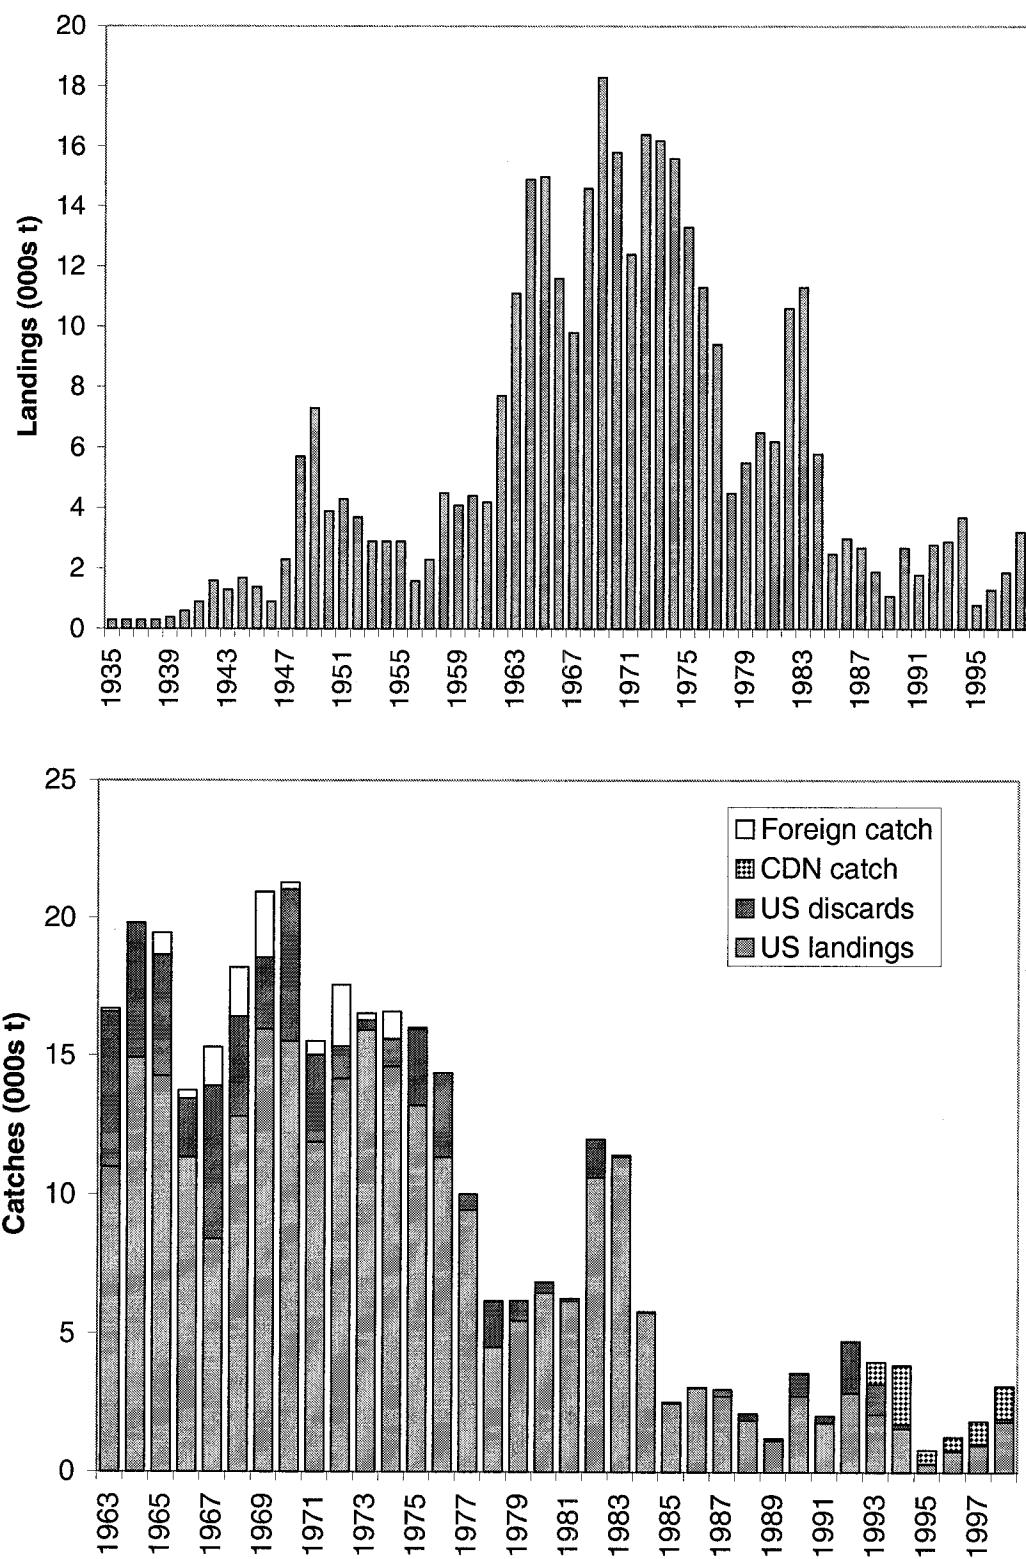

Fig. 2 . Landings of Georges Bank yellowtail flounder by Canada and the United States. The top panel shows landings (exclusive of discarding) from 1935 – 1998, and the bottom panel shows the national composition of catches from 1963 – 1998.

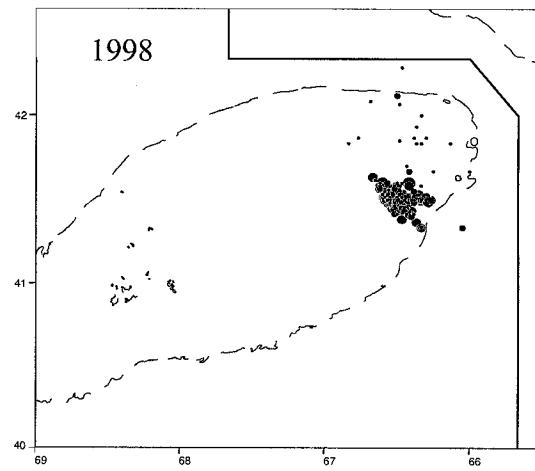

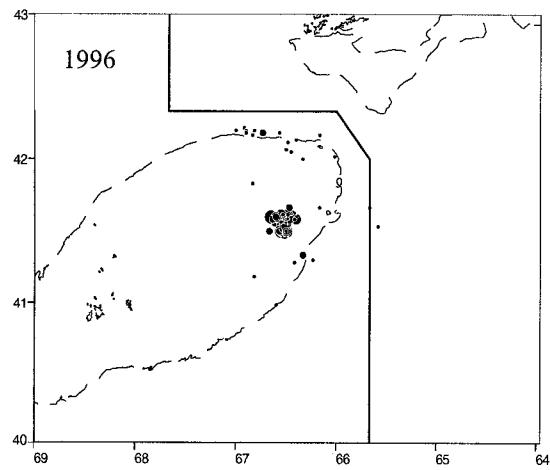

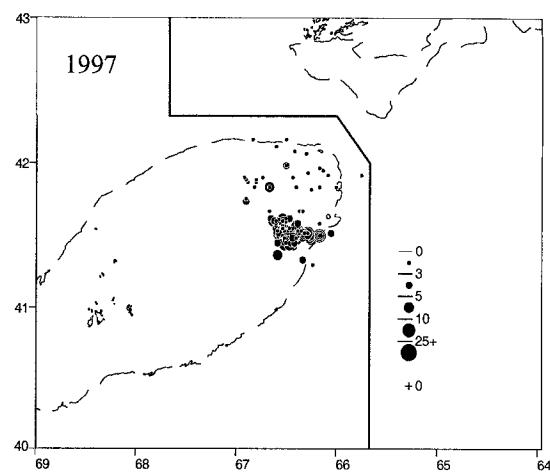

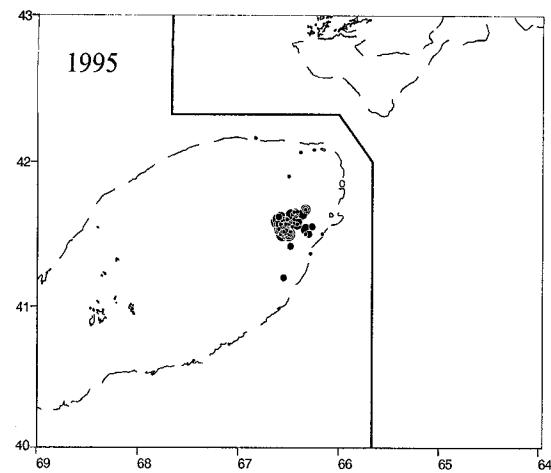

Fig 3. Distribution of Canadian mobile gear (TC 2 & 3) effort for 1995-98 where trip landings of yellowtail were > 0.5t, expanding symbols represent metric tonnes.

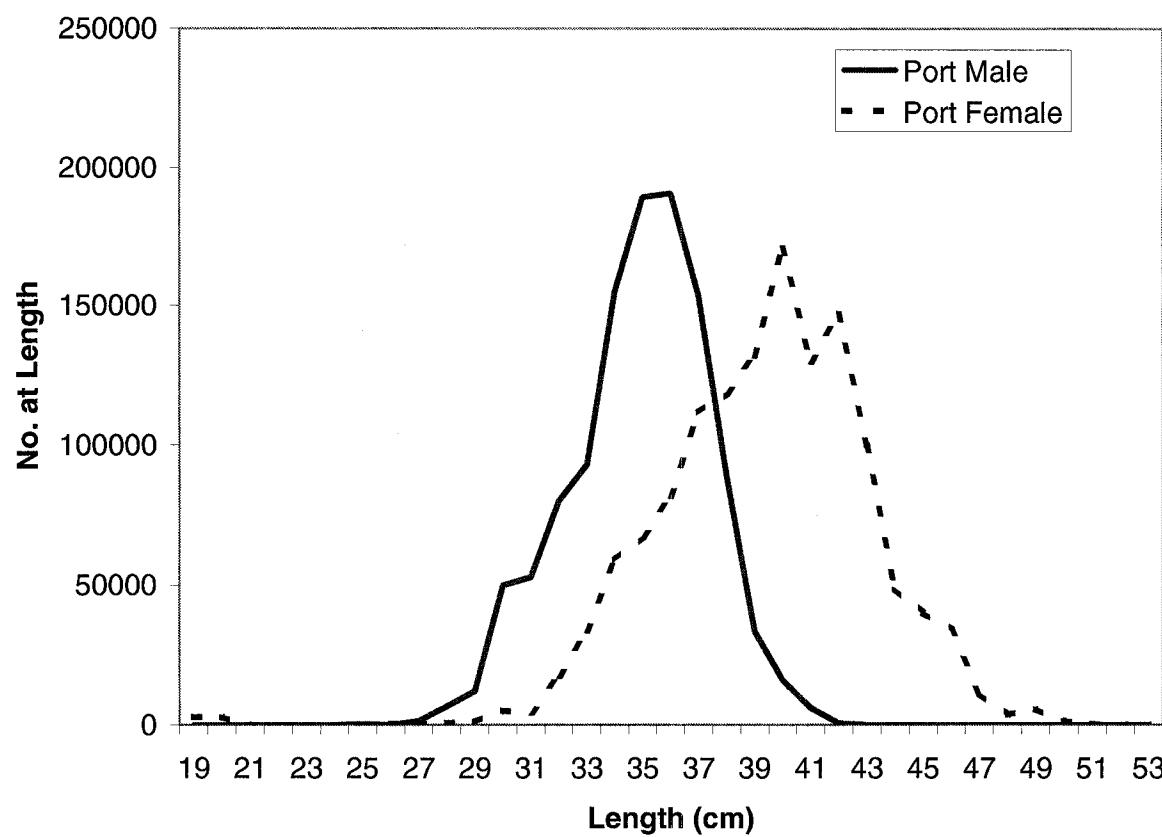

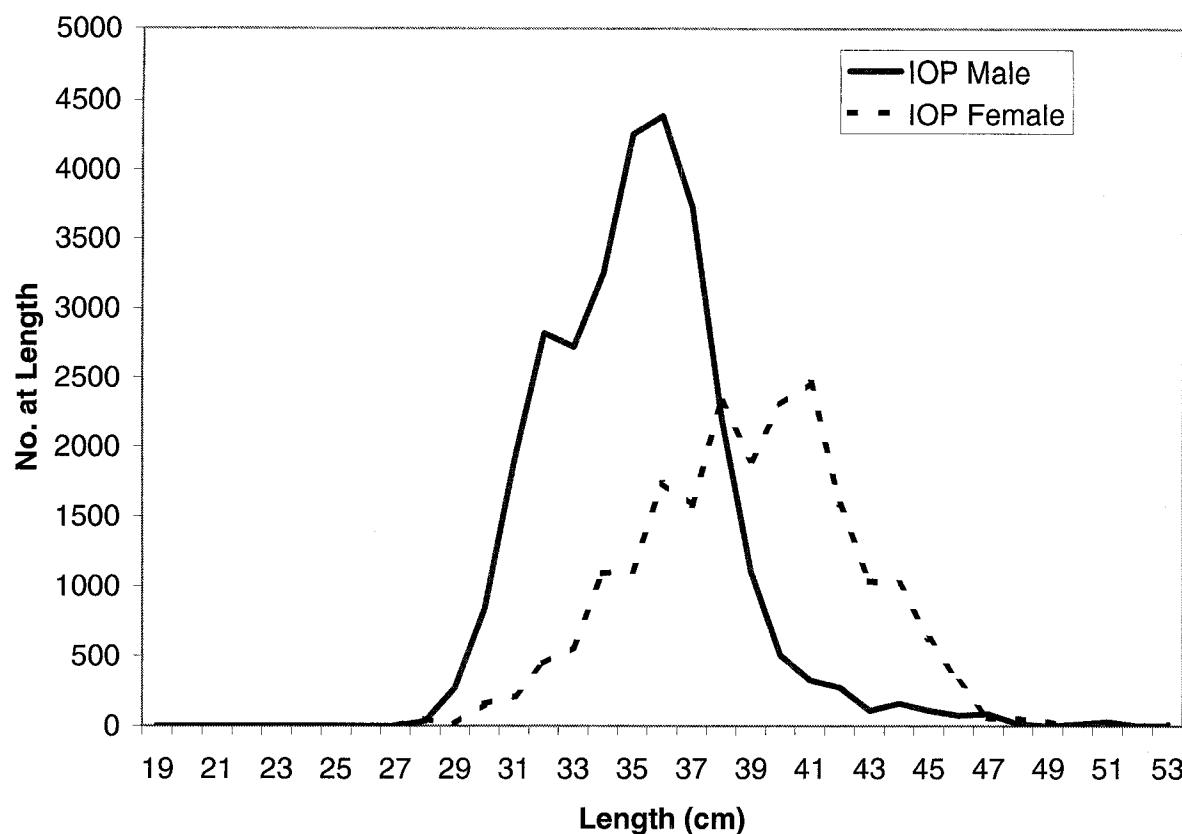

Fig. 4. Comparison of length frequency distributions of samples observed in 1998 by port technicians (Port) with those at sea samples collected with the Observer Program (IOP), 1998, Georges Bank.

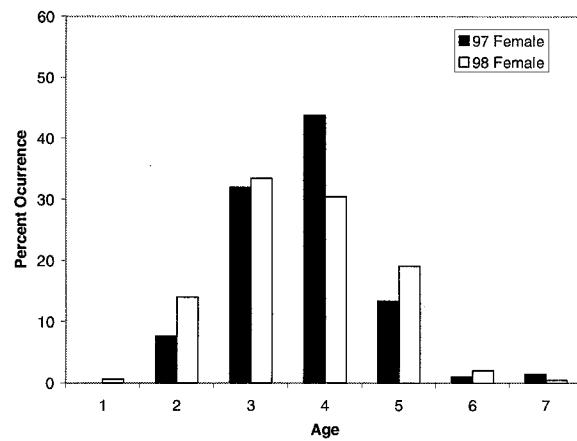

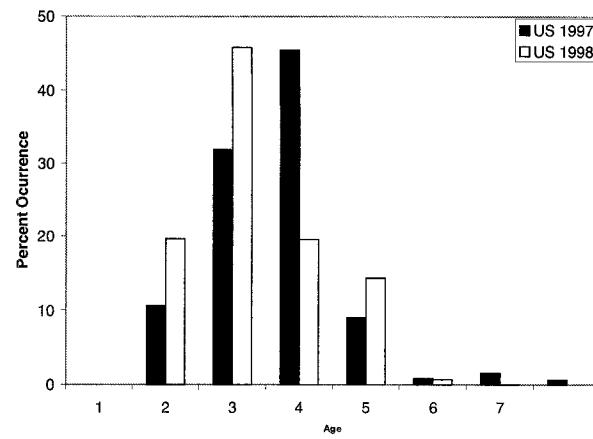

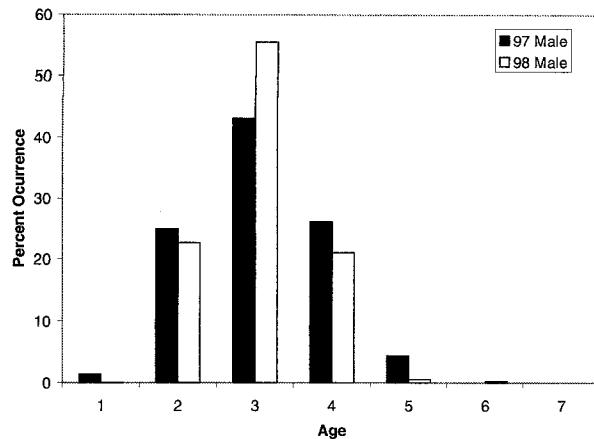

Fig. 5. Comparison of yellowtail flounder fishery age composition, 1997 and 1998, for Canadian (left panels, males and females) and USA (right panel, sexes aggregated) catches on Georges Bank.

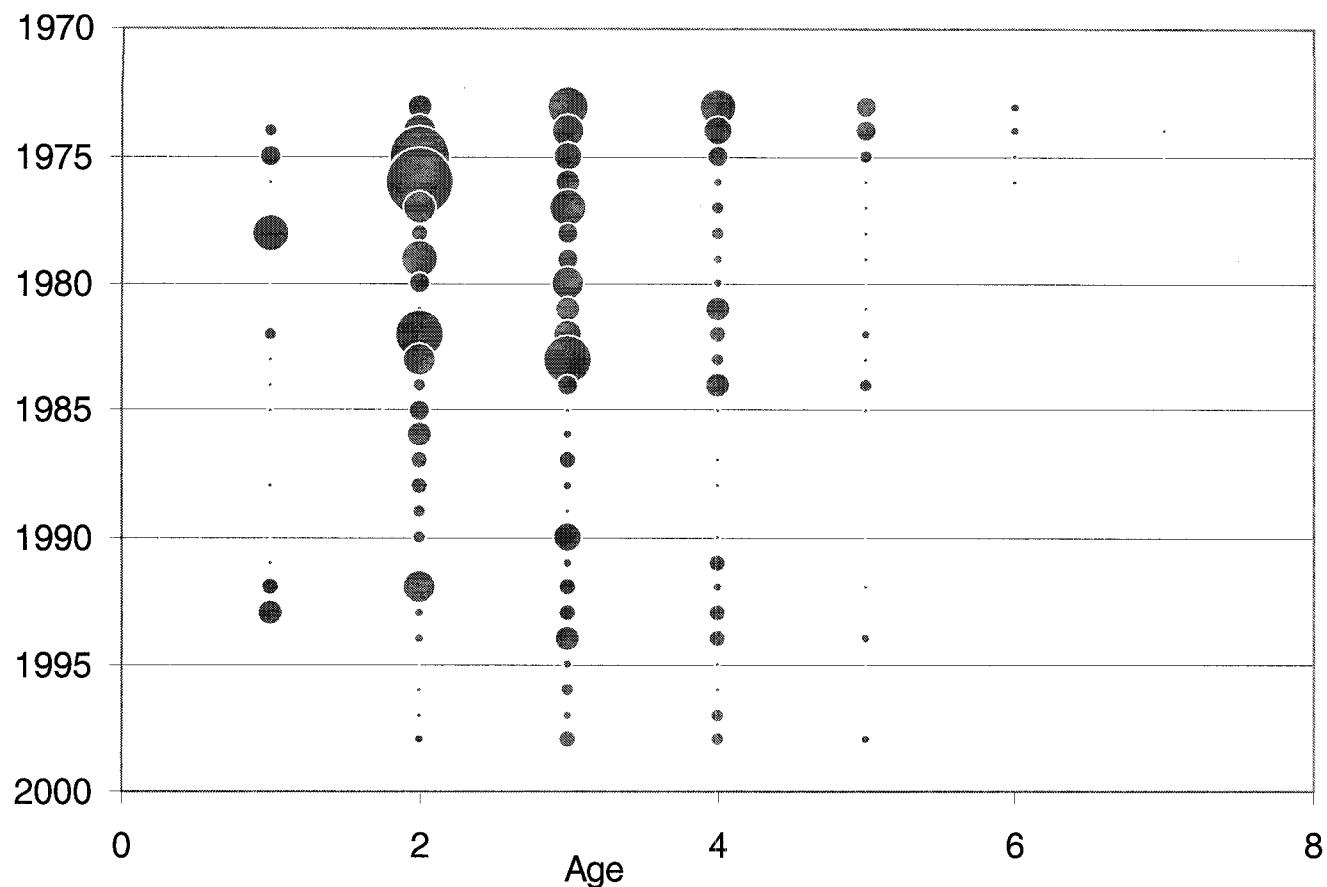

Fig. 6. Bubble plot in which the area of the bubble is proportional to the magnitude of the catch at age for Georges Bank yellowtail flounder, Canada and USA fisheries combined. Refer to Table 3 for the absolute value of the catch at age.

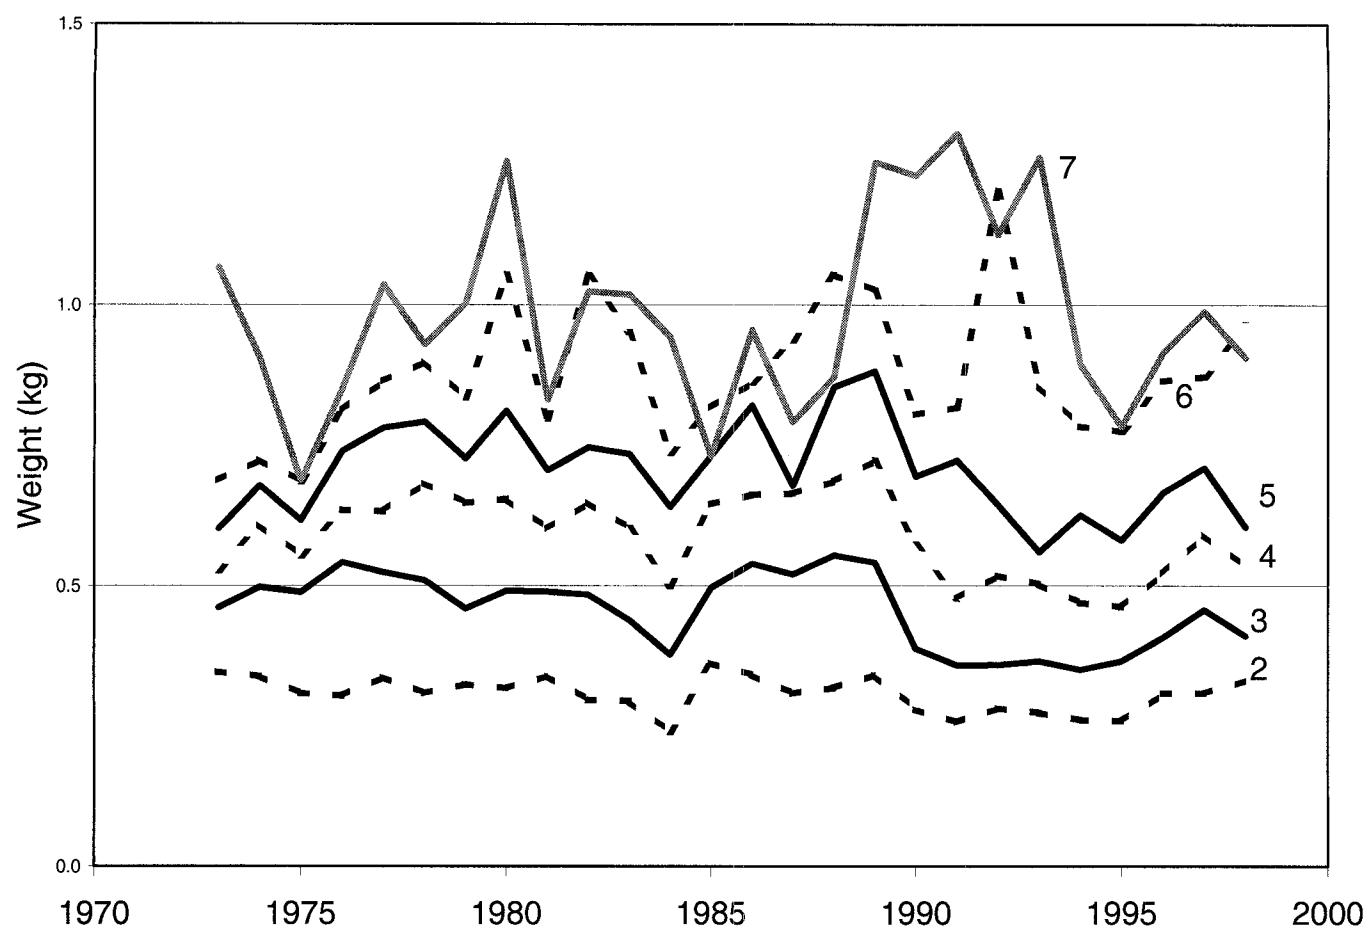

Fig. 7. Trend in mean weight at age from the 5Zjhmn yellowtail fishery, 1973 to 1998 (Canada and USA).

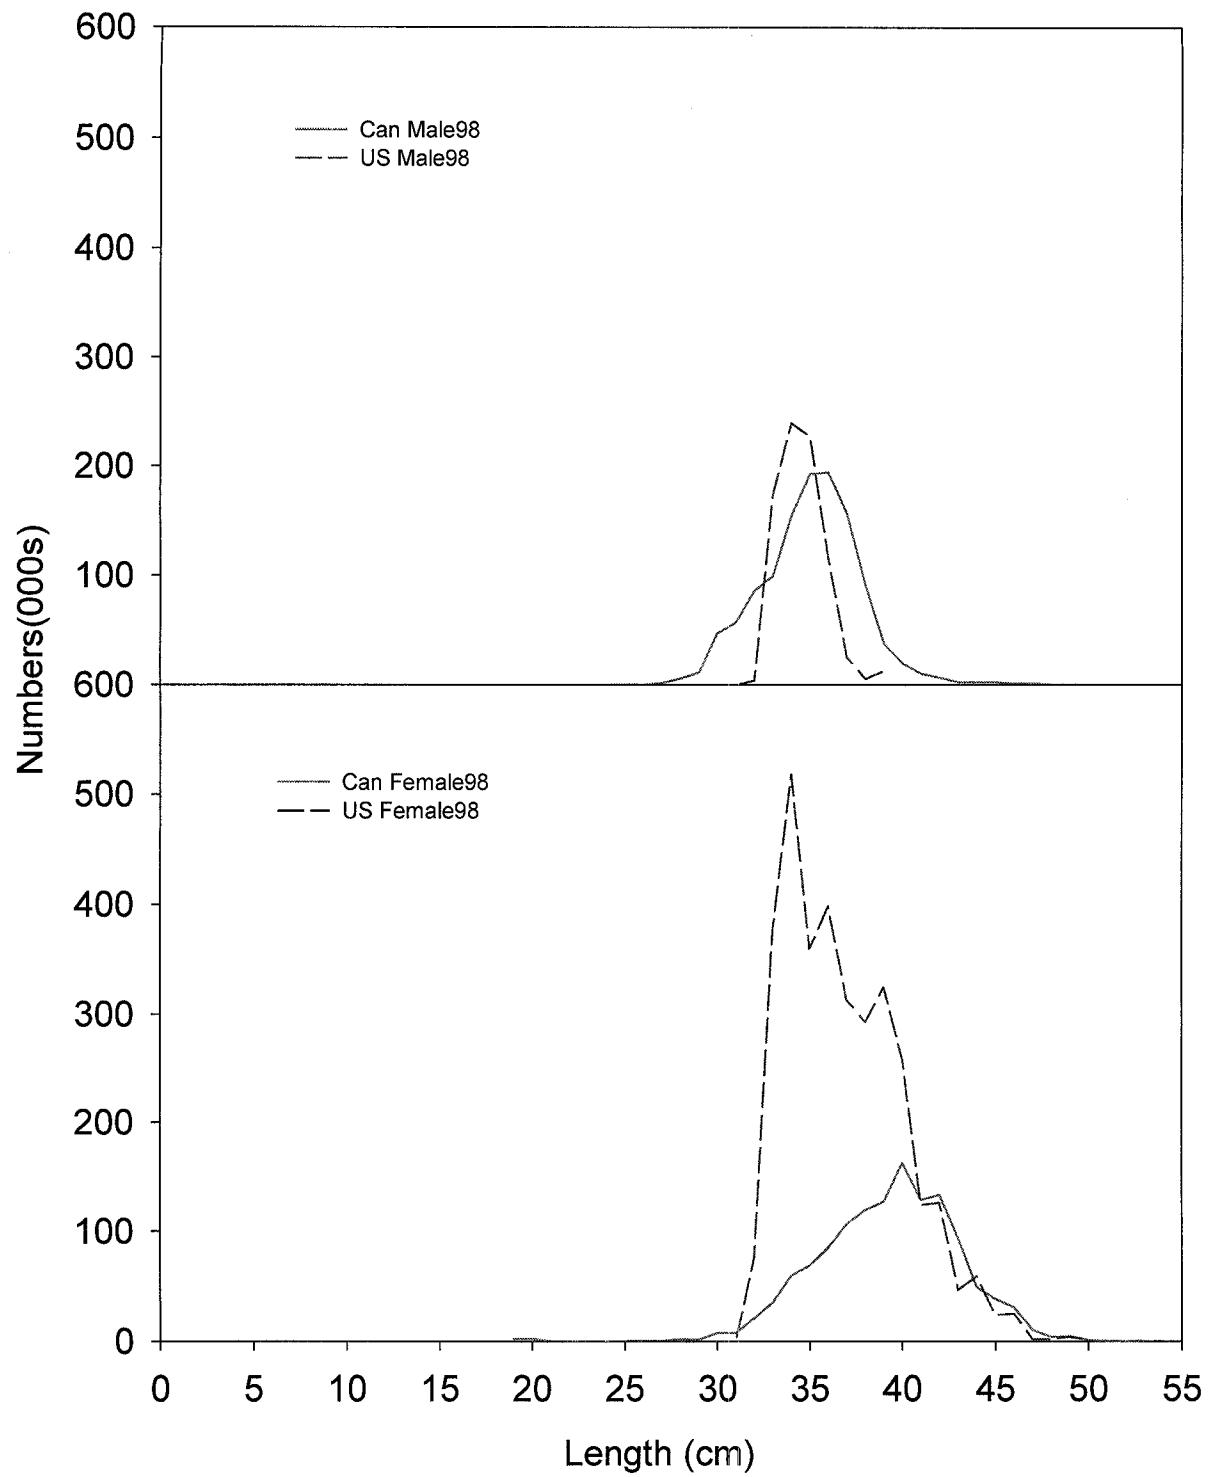

Fig. 8. Comparison of 5Zjhmn yellowtail fishery length composition in 1998 (Canada and USA).

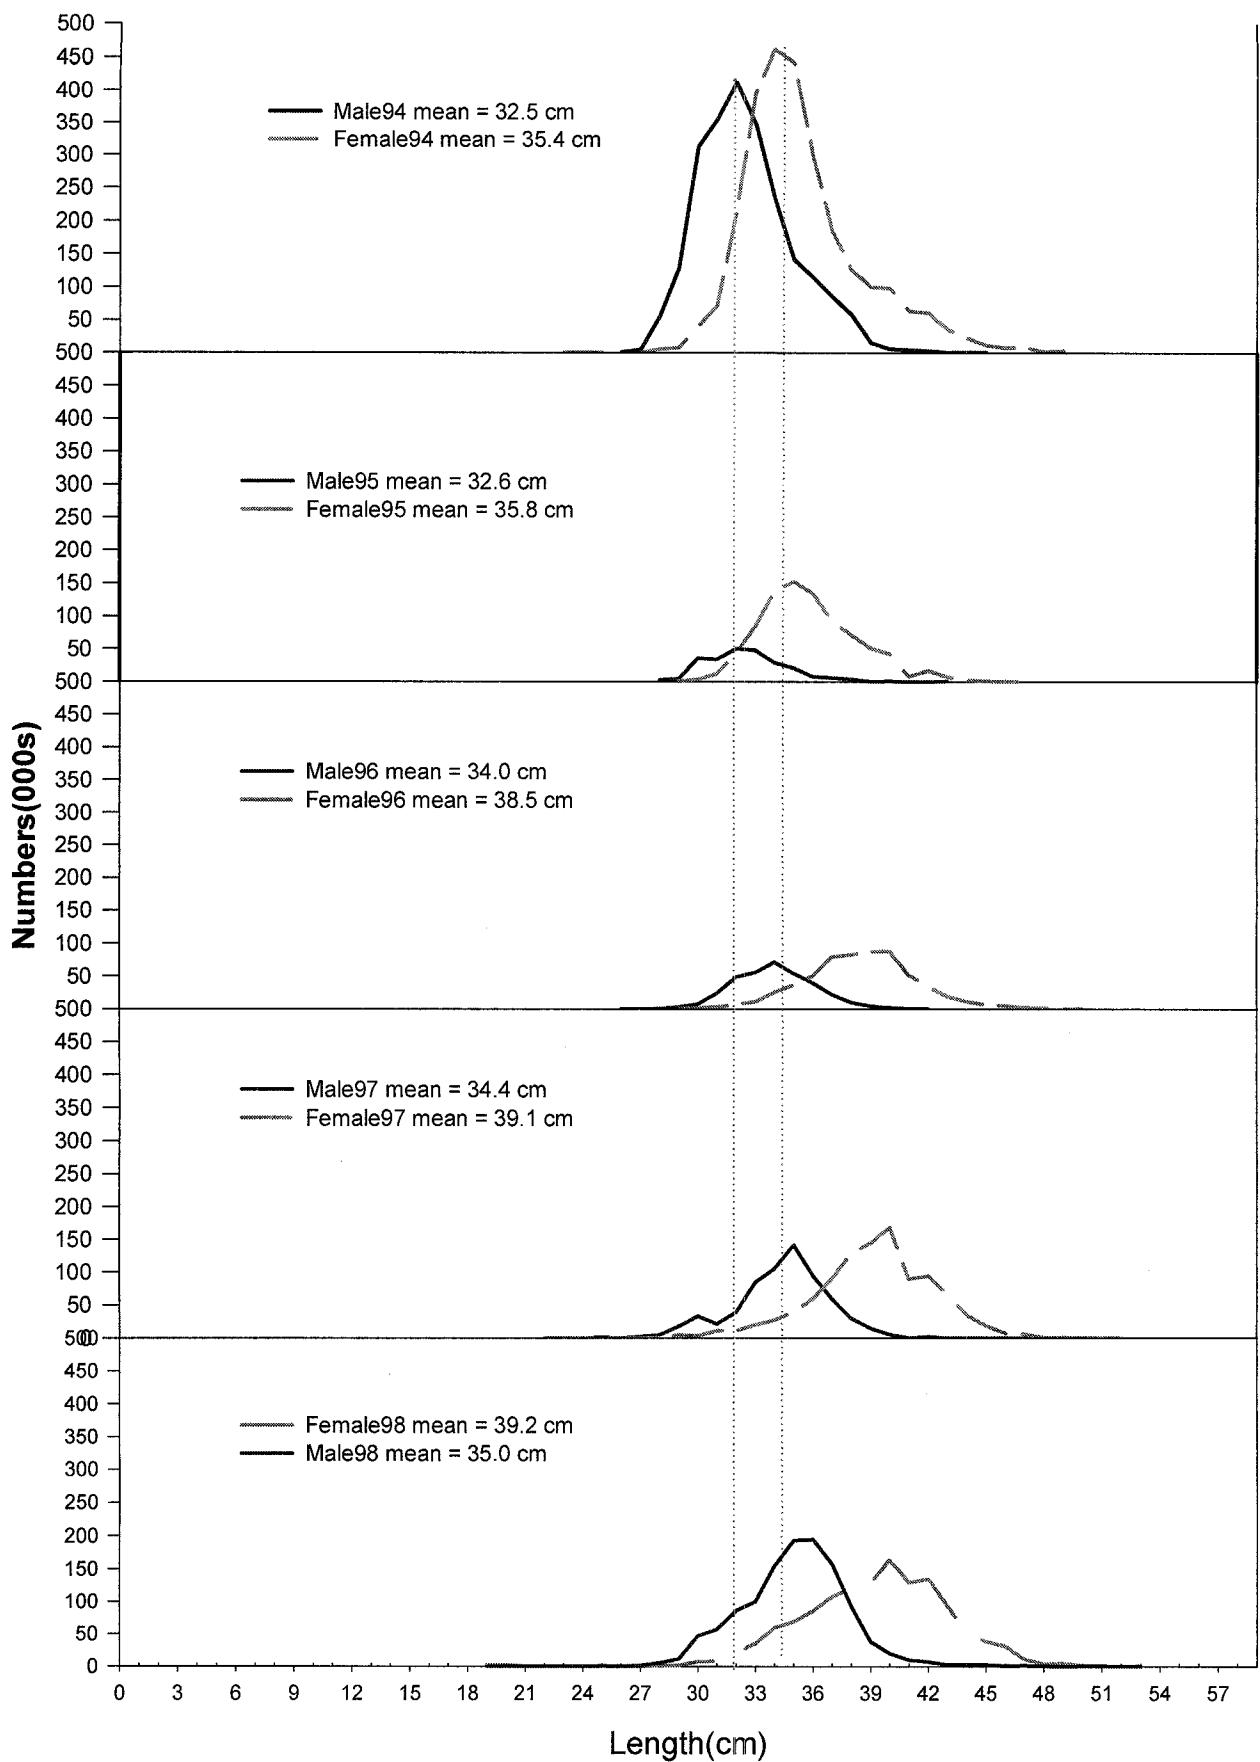

Fig. 9. Comparison of the yellowtail flounder length frequency composition taken in the Canadian Georges Bank fishery from 1994 to 1998.

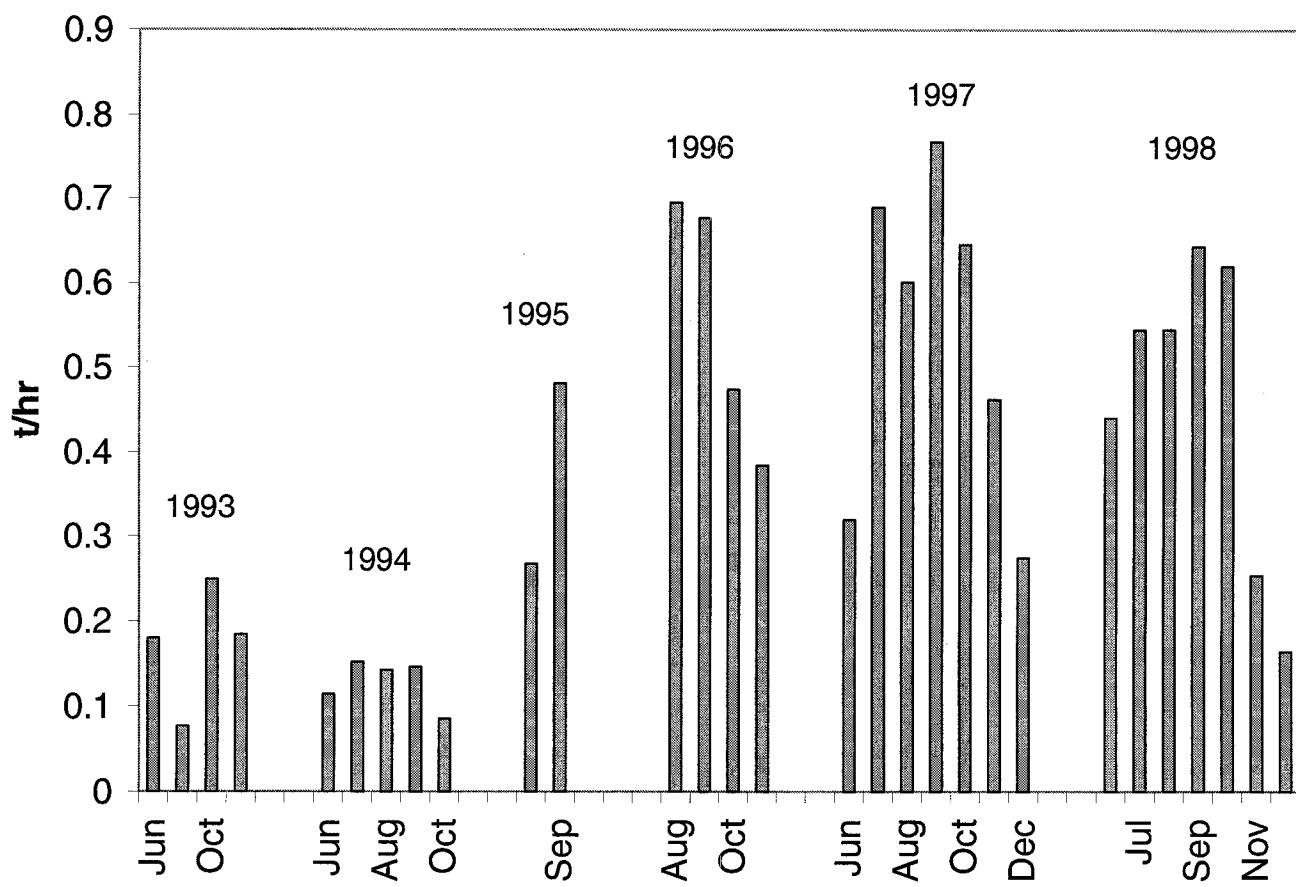

Fig. 10. Mean monthly catch rates of stern trawlers (TC 2-3), Georges Bank Yellowtail flounder, 1993 to 1998. Selected records included 5Zm only.

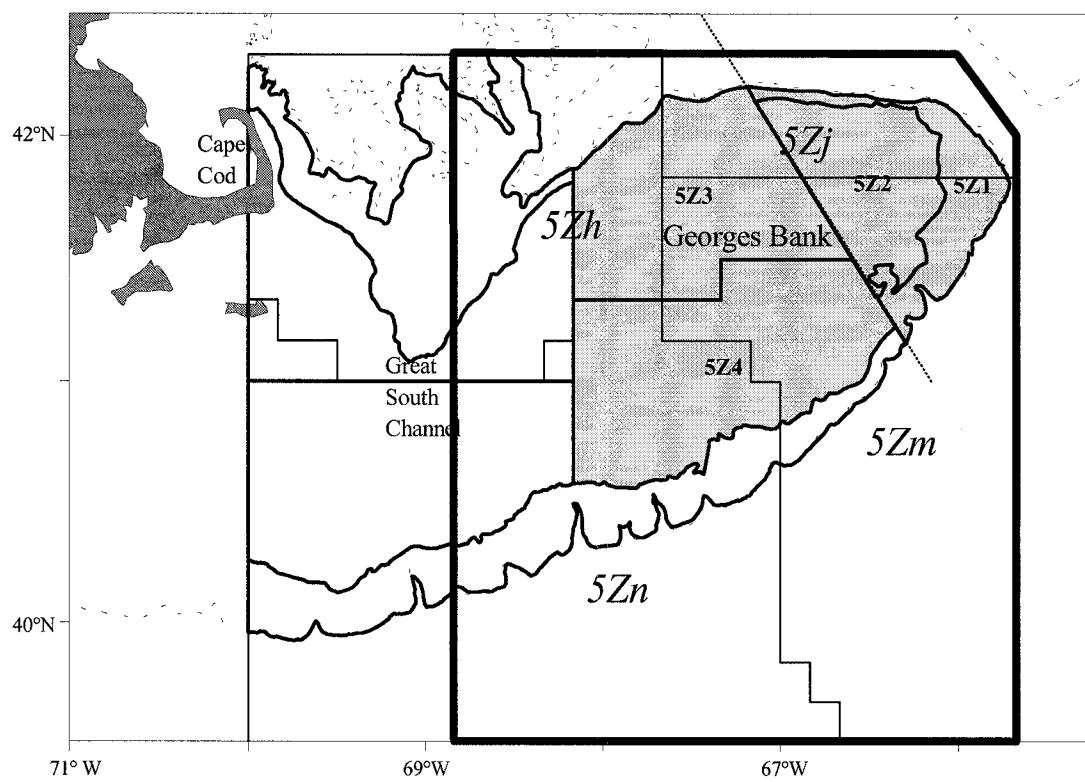

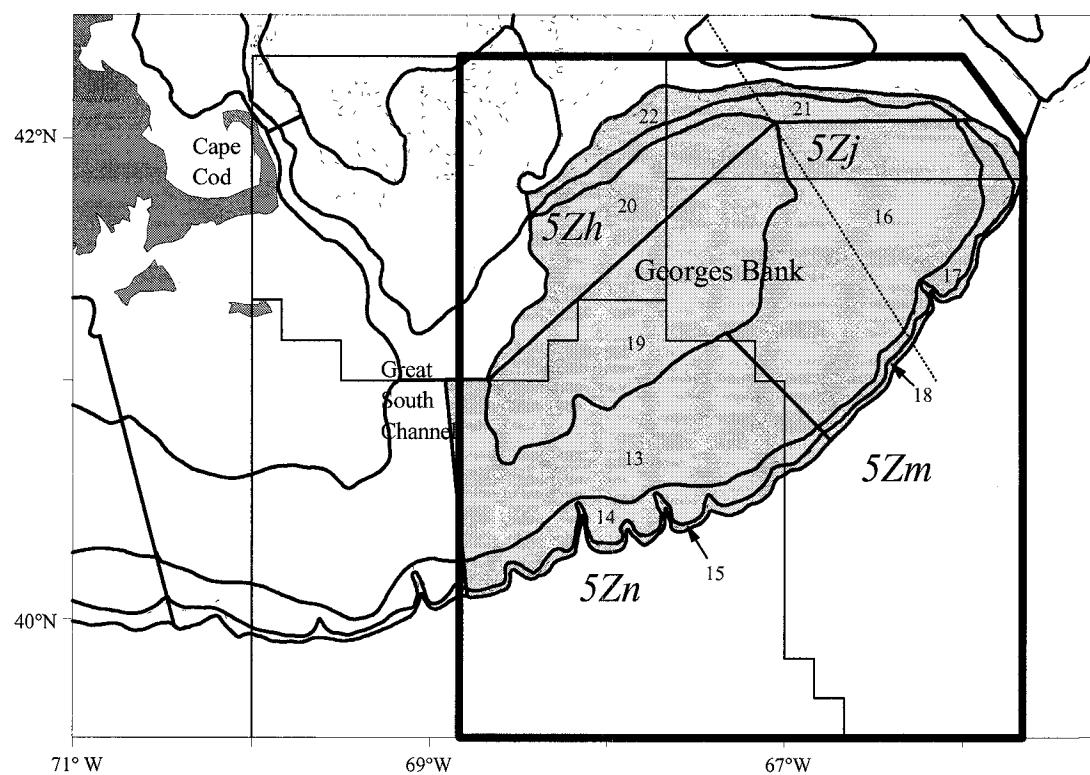

Fig. 11. USA (top) and Canadian (bottom) strata used to derive research survey abundance indices for Georges Bank groundfish surveys.

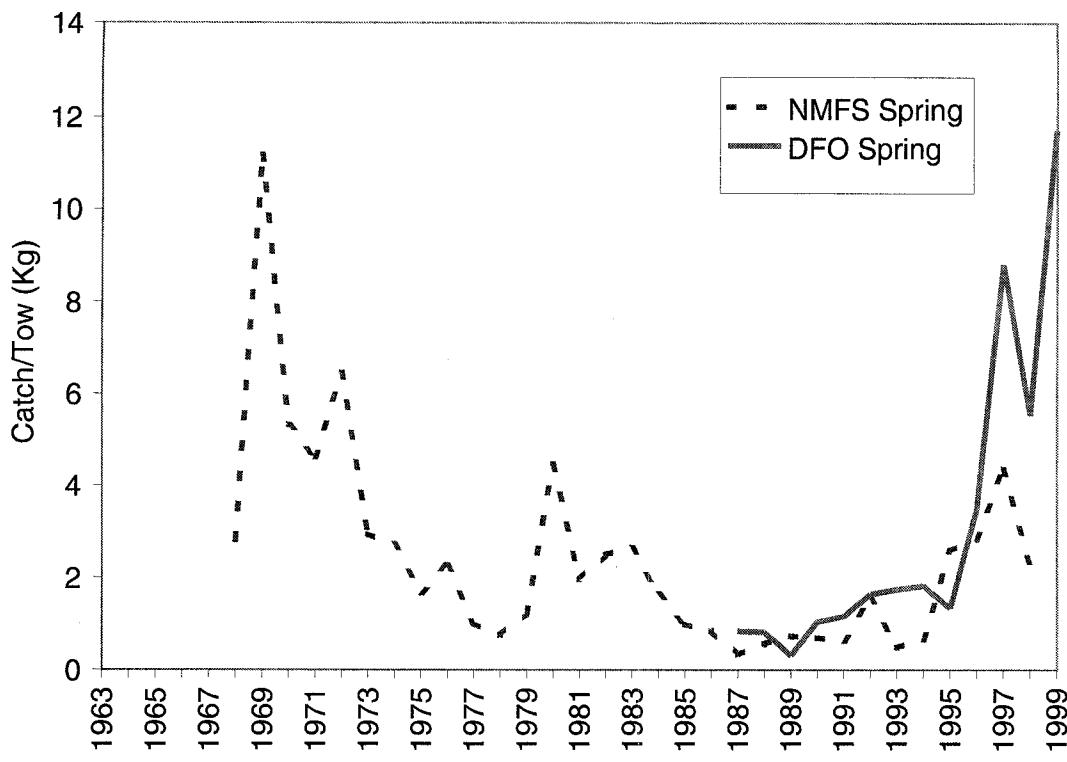

Fig. 12. NMFS and DFO spring survey results for yellowtail flounder (Strata 5Z1-4), 1987-1998 (the series includes 1999 for the DFO survey; the Canadian series was also adjusted for catchability differences).

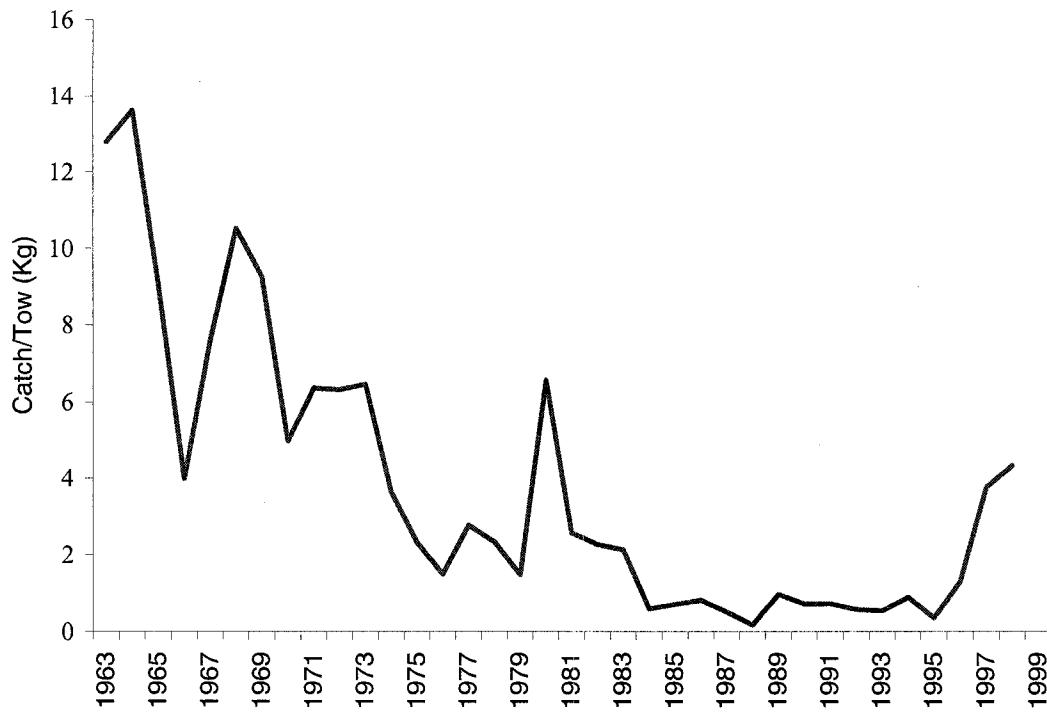

Fig. 13. NMFS fall survey results for yellowtail flounder on Georges Bank, 1963-1998.

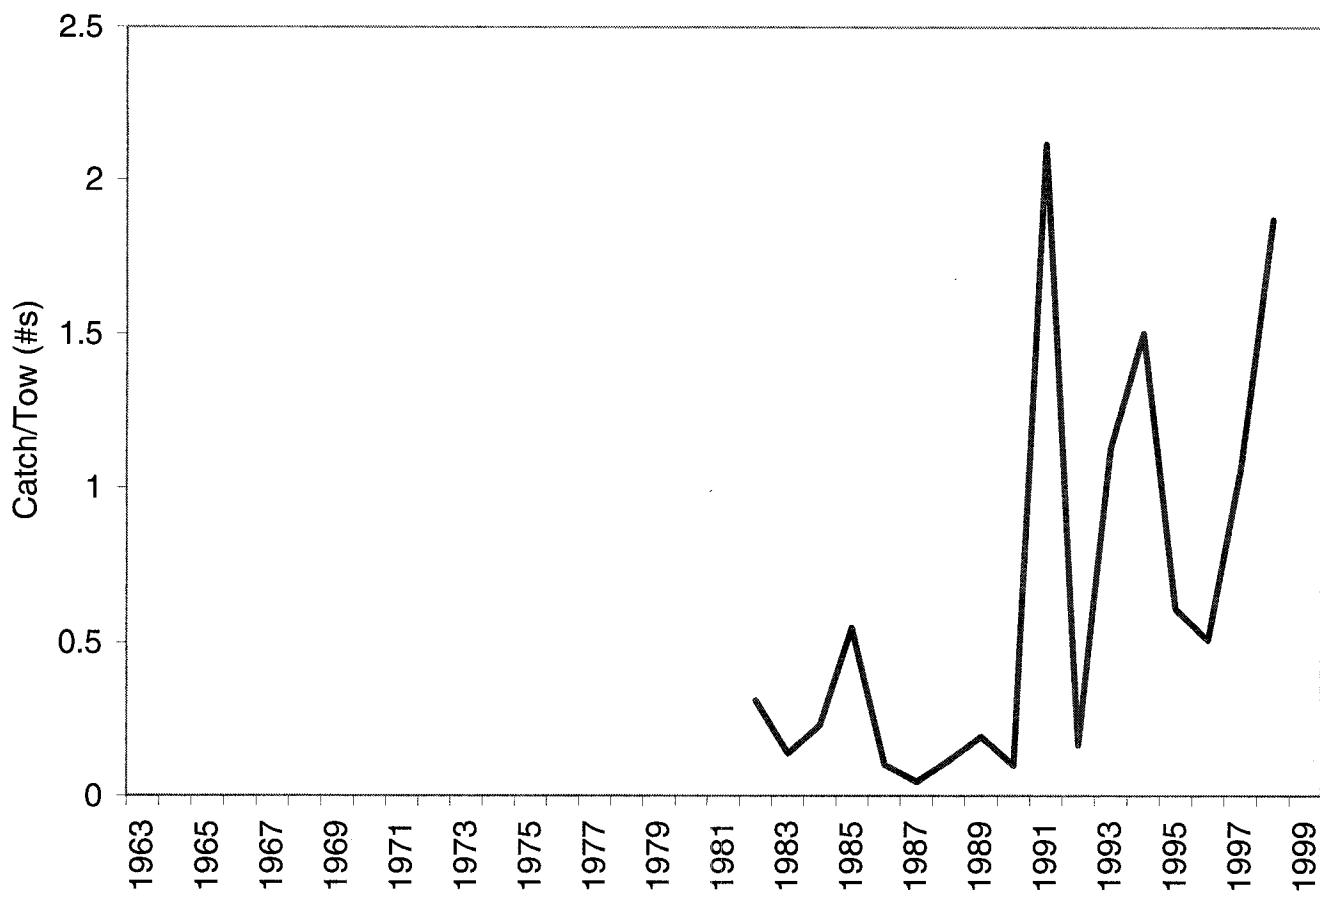

Fig. 14. Catches of yellowtail flounder in the NMFS scallop survey, Georges Bank.

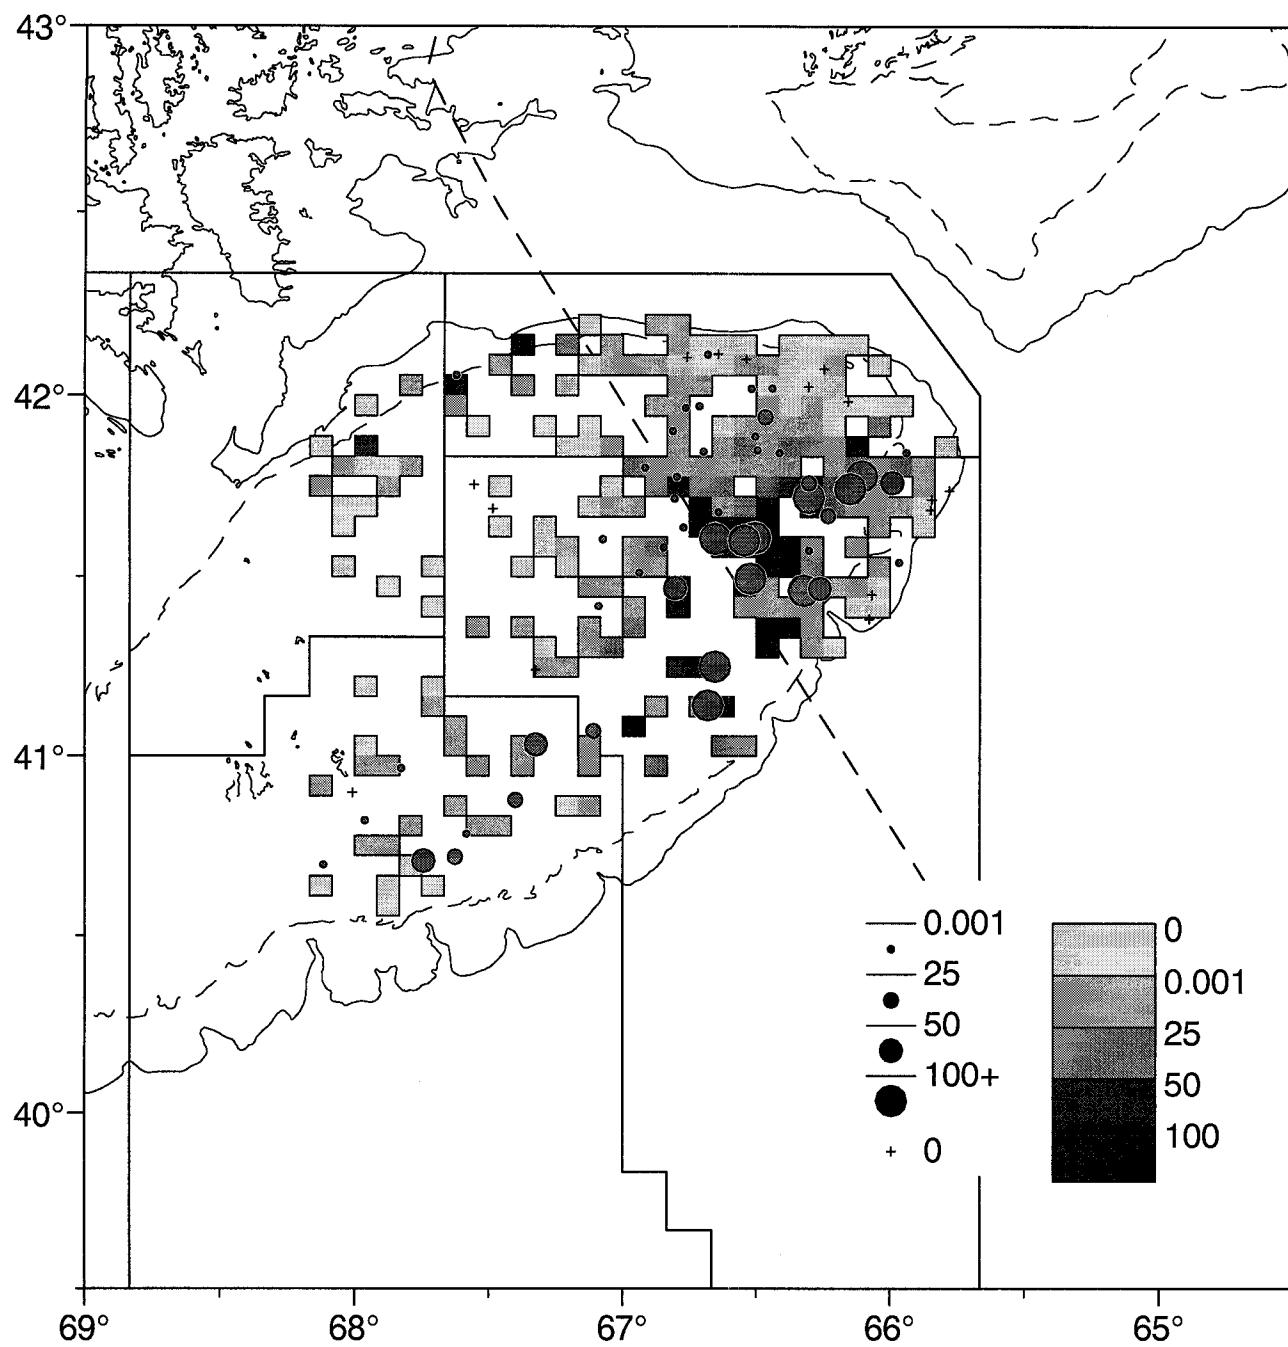

Fig. 15. The distribution of catches (#/tow) of yellowtail flounder (solid circles) in the DFO Georges Bank spring survey in 1999 compared with the average distribution in the previous five years (shaded rectangles), averaged by 3' squares.

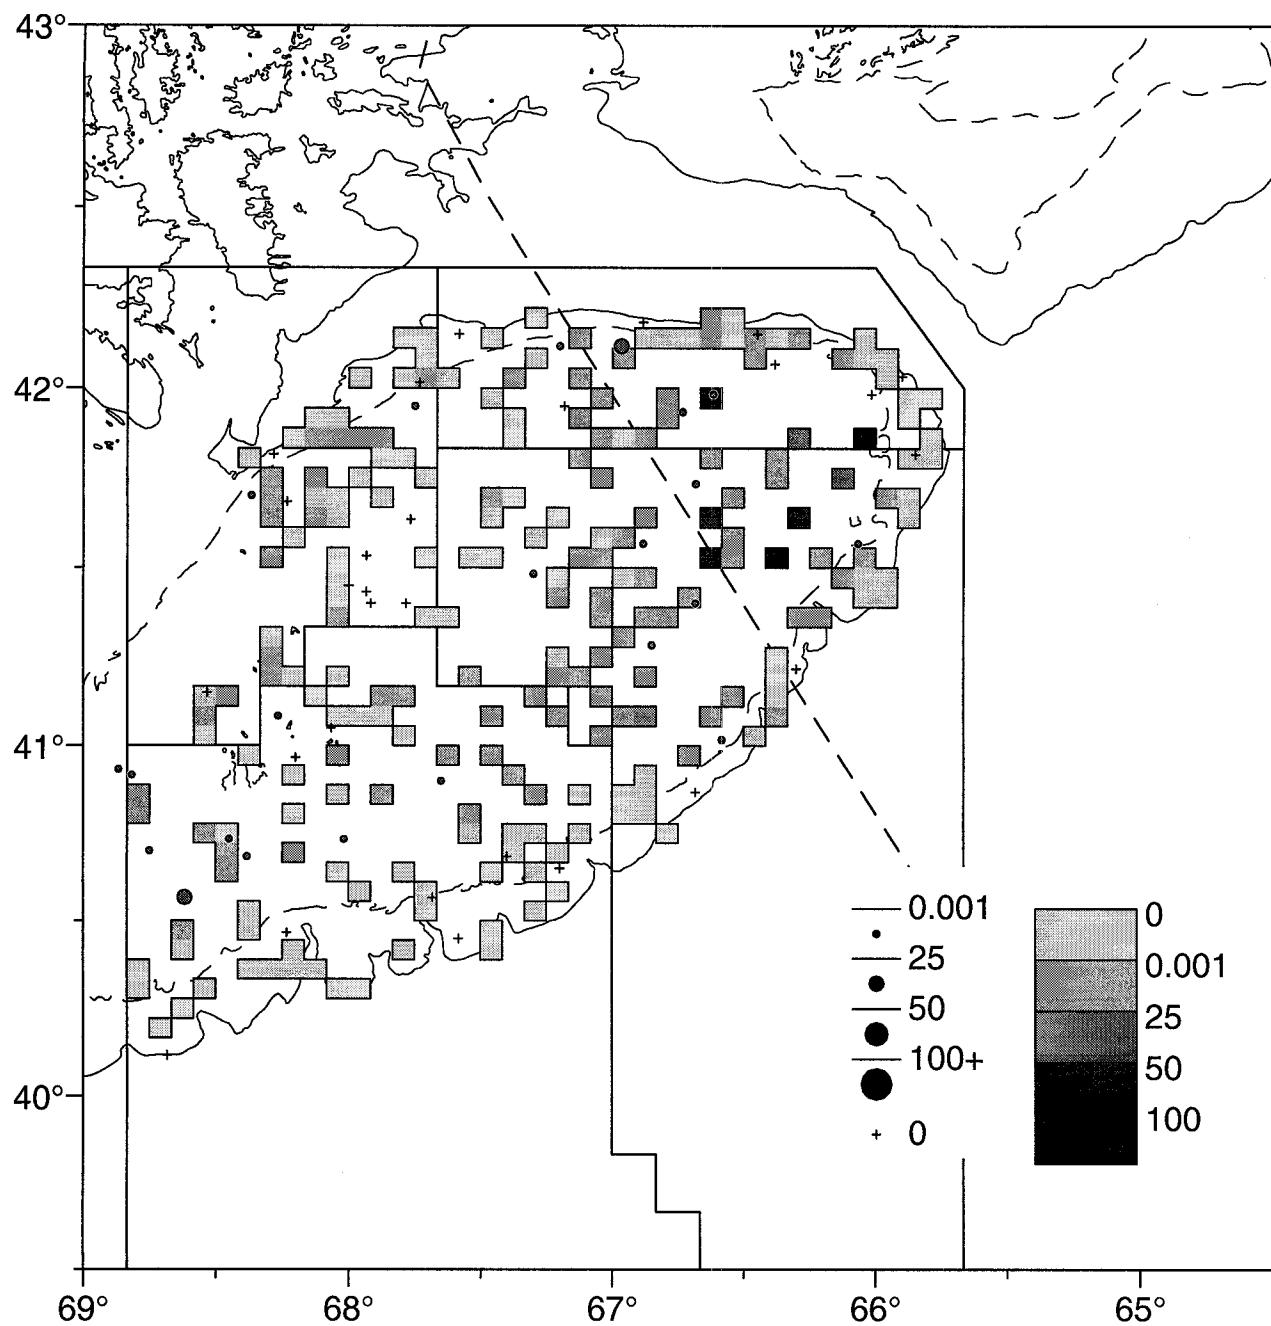

Fig. 16. The distribution of catches (#/tow) of yellowtail flounder in the NMFS Georges Bank spring survey in 1998 (solid circles), compared with the average distribution in the previous five years (shaded rectangles), averaged by 3' squares.

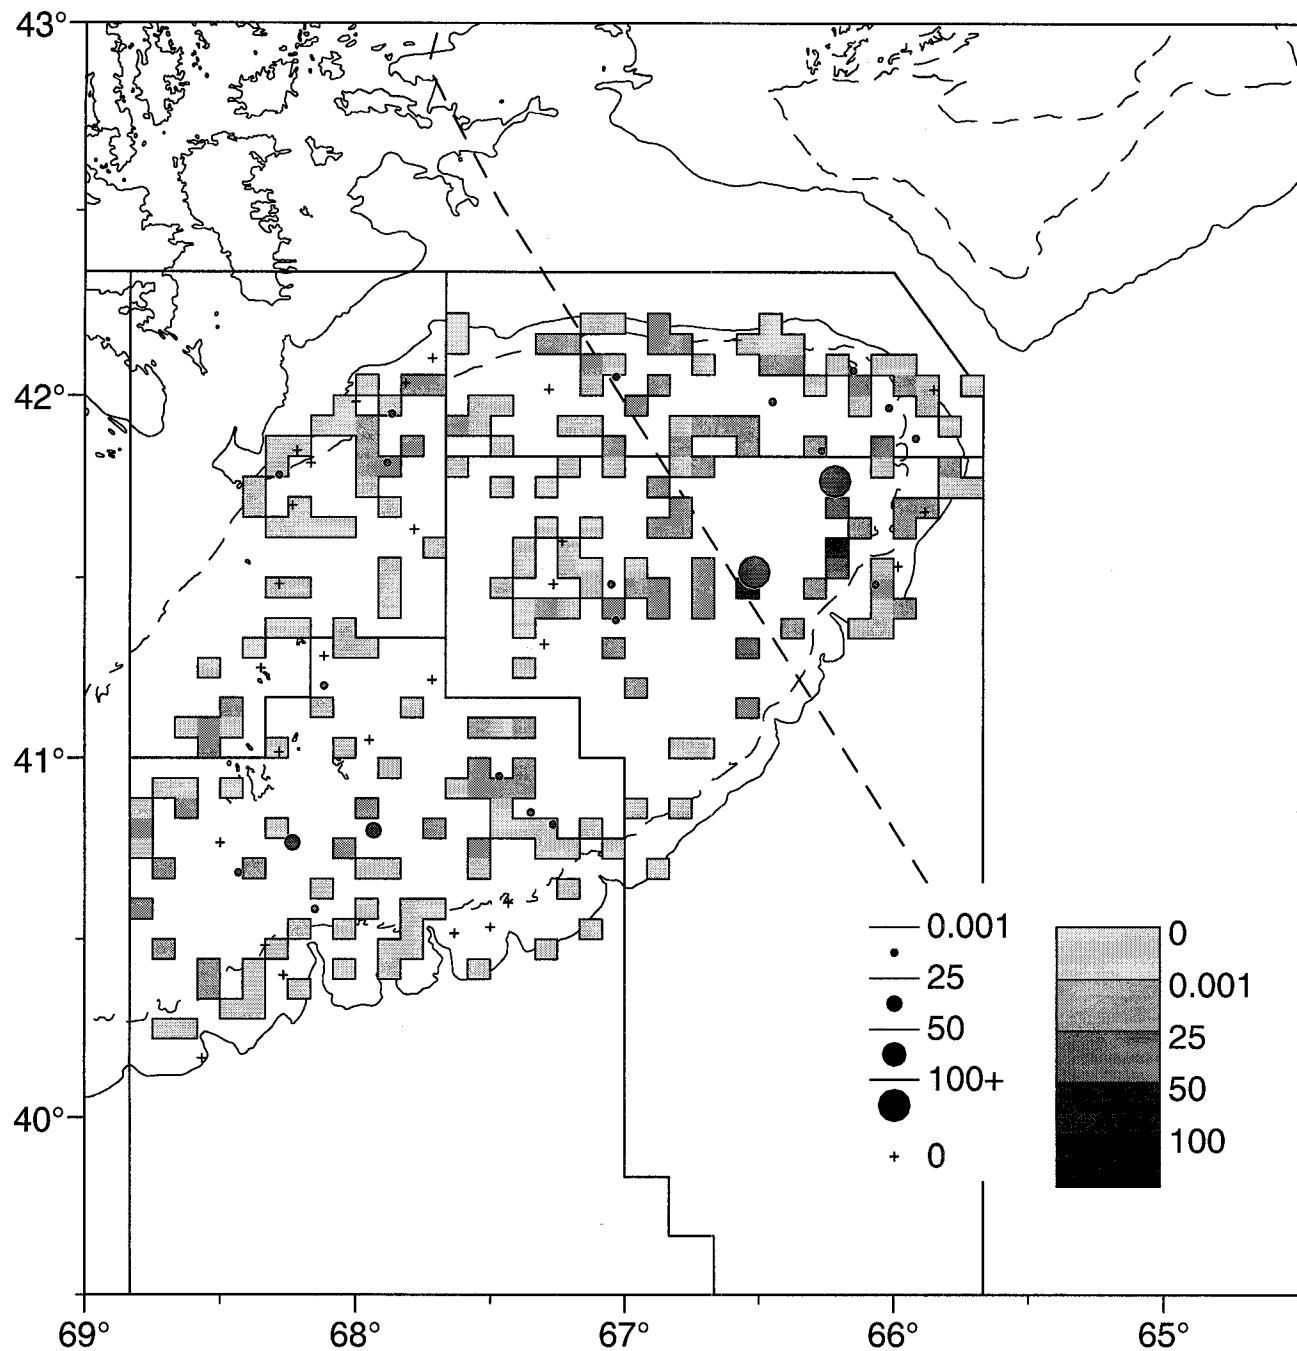

Fig. 17. The distribution of catches (#/tow) of yellowtail flounder in the NMFS Georges Bank fall survey in 1998 (solid circles), compared with the average distribution in the previous five years (shaded rectangles), averaged by 3' squares.

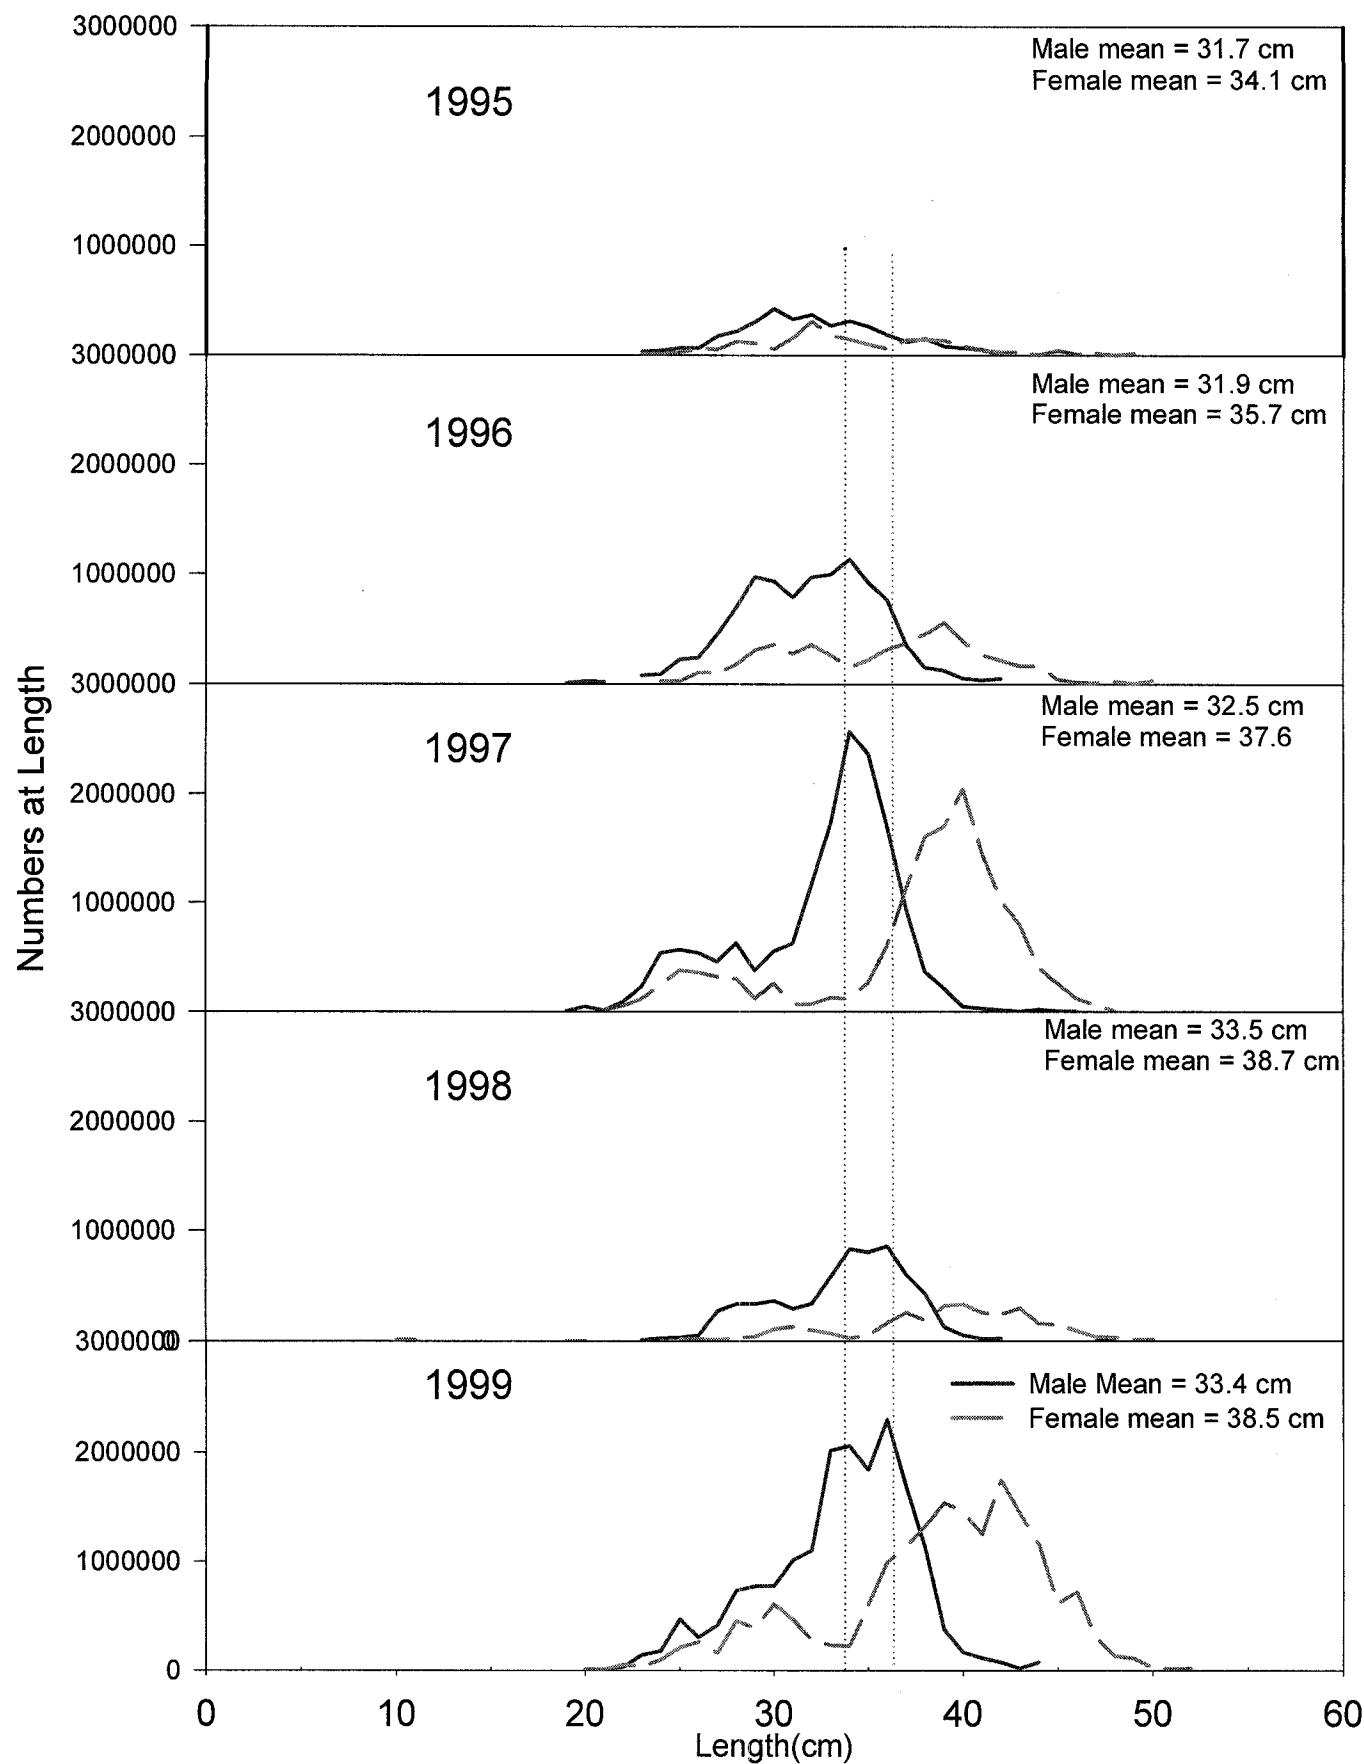

Fig. 18. Comparison of yellowtail flounder length composition in DFO spring surveys, 1995 - 1999, Georges Bank.

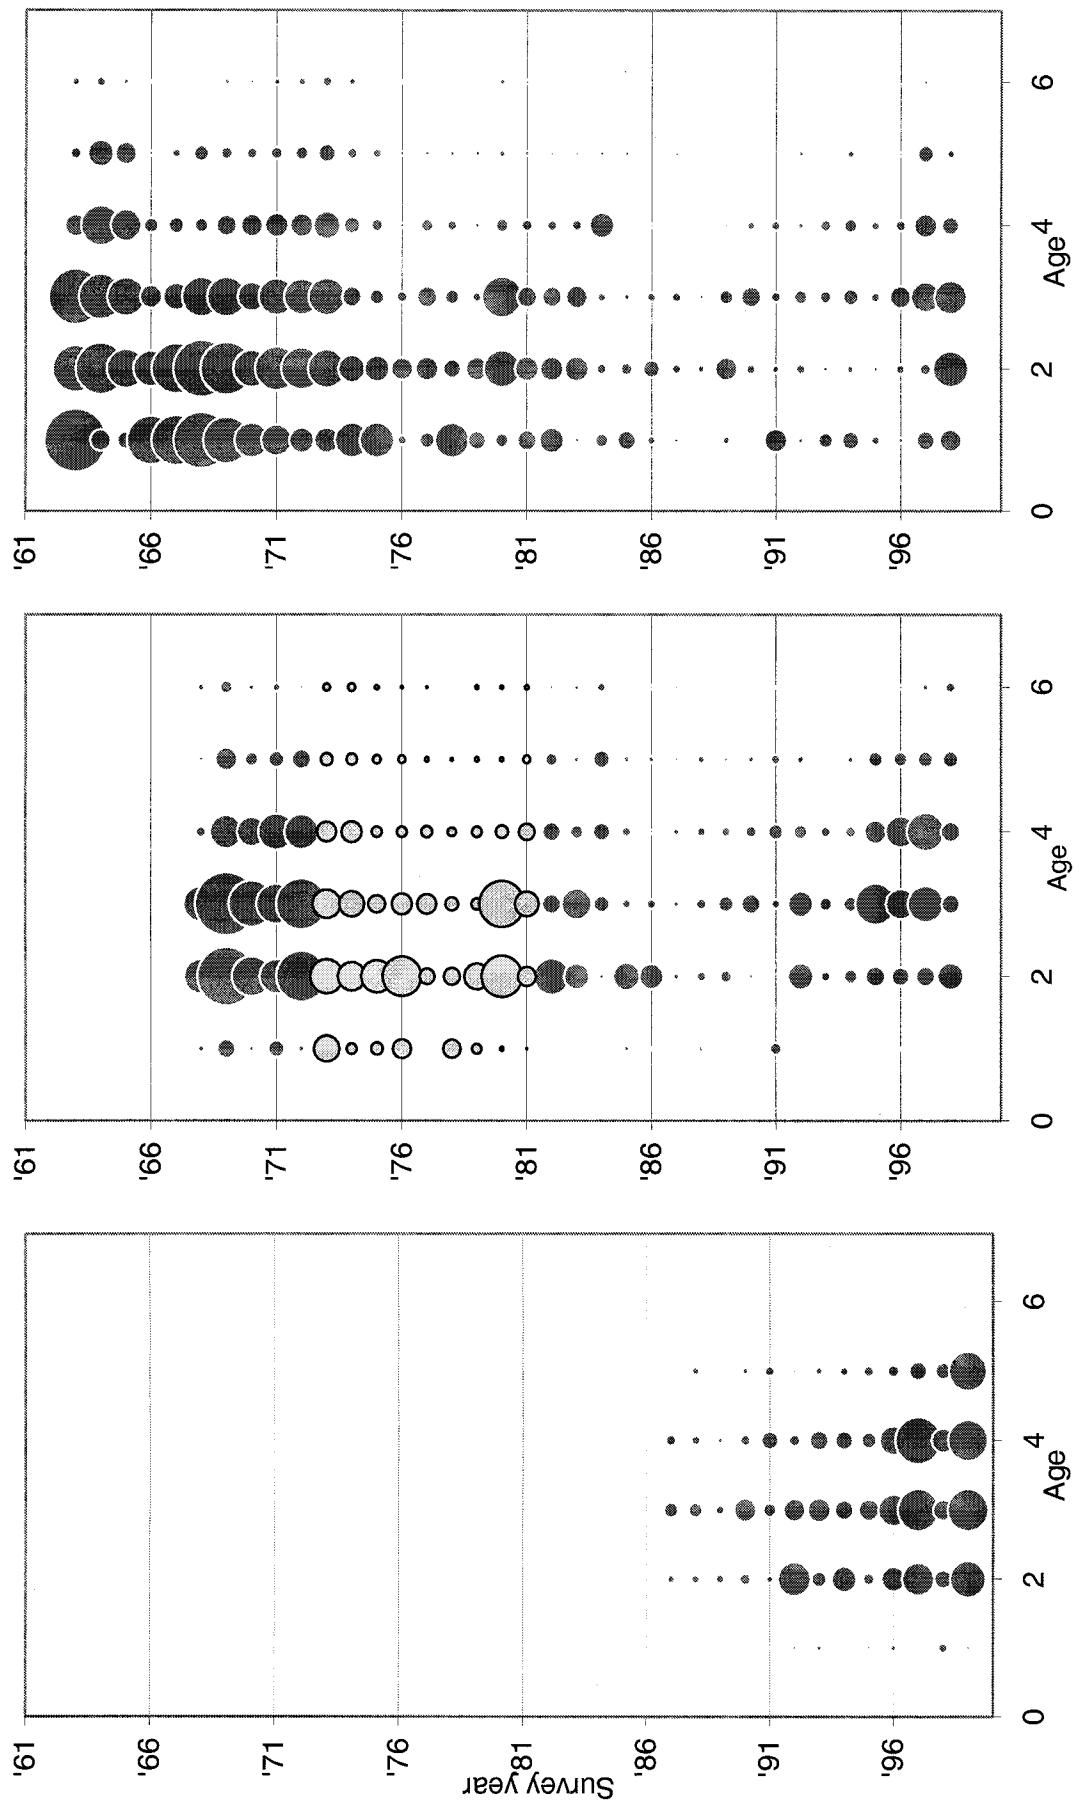

Fig. 19. Bubble plot in which the area of the bubble is proportional to the magnitude of the indices of abundance for the DFO spring (left), NMFS spring (middle), and NMFS fall (right) surveys. The grey shaded symbols in the USA spring series denote the period when the Yankee – 41 net was used. Refer to Tables 5, 6 and 7 for the absolute value of the indices.

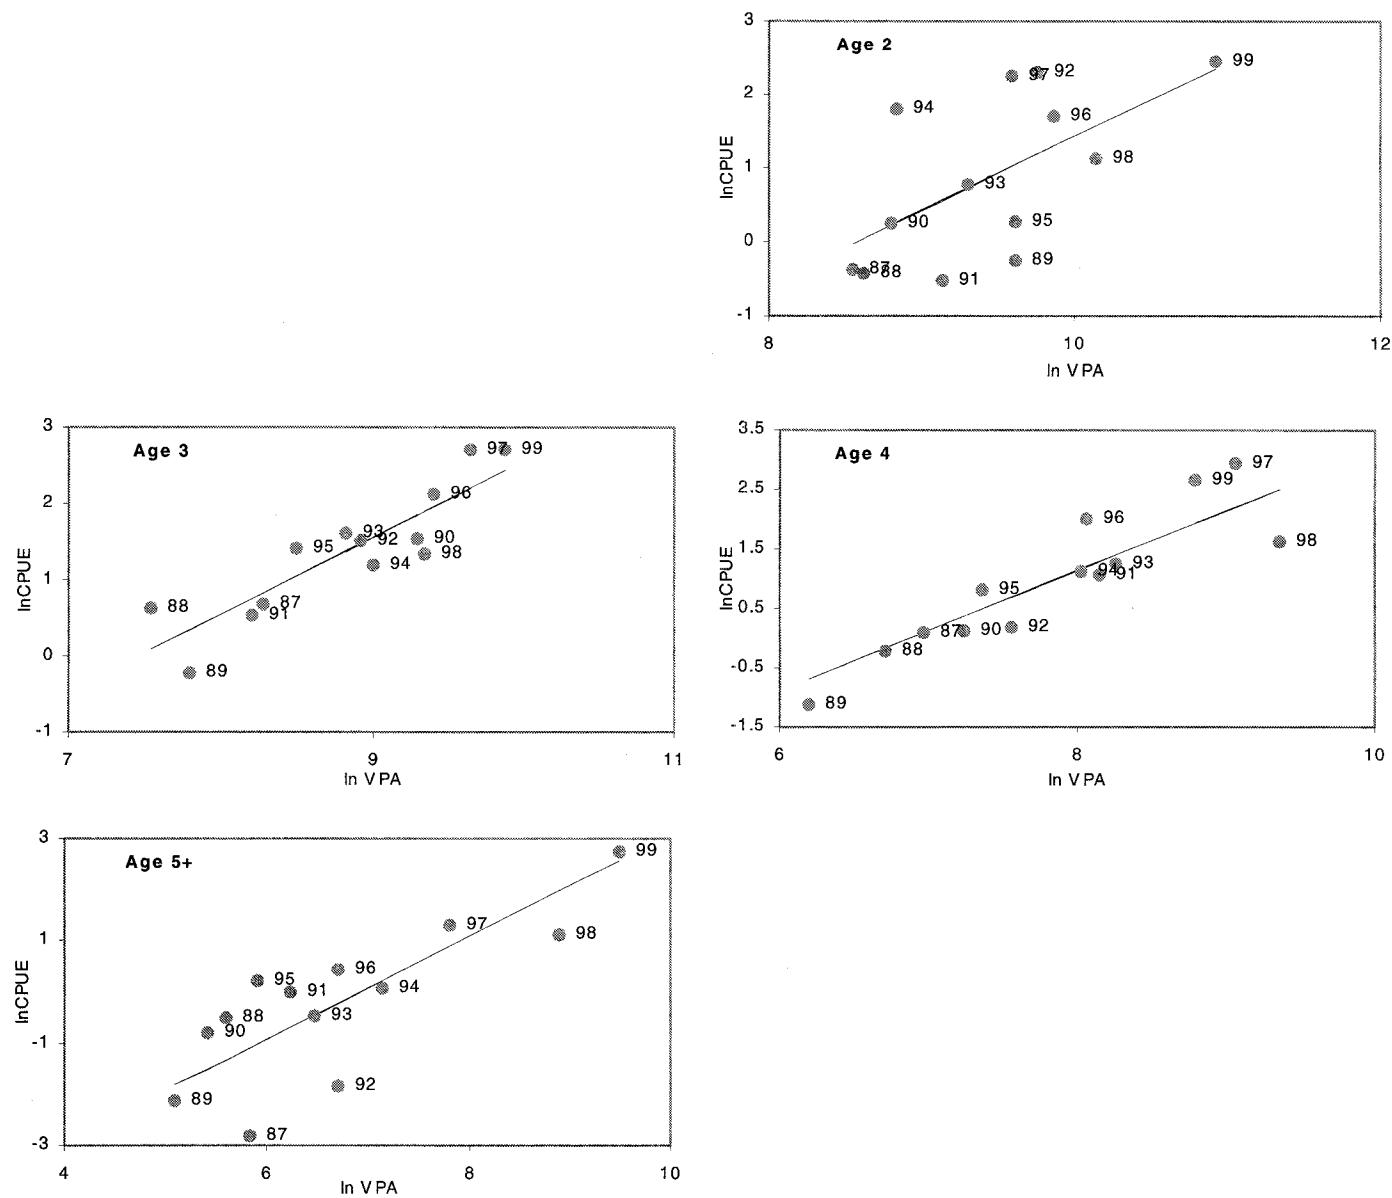

Fig. 20. Age by age residual plots for the DFO spring survey, Georges Bank yellowtail flounder.

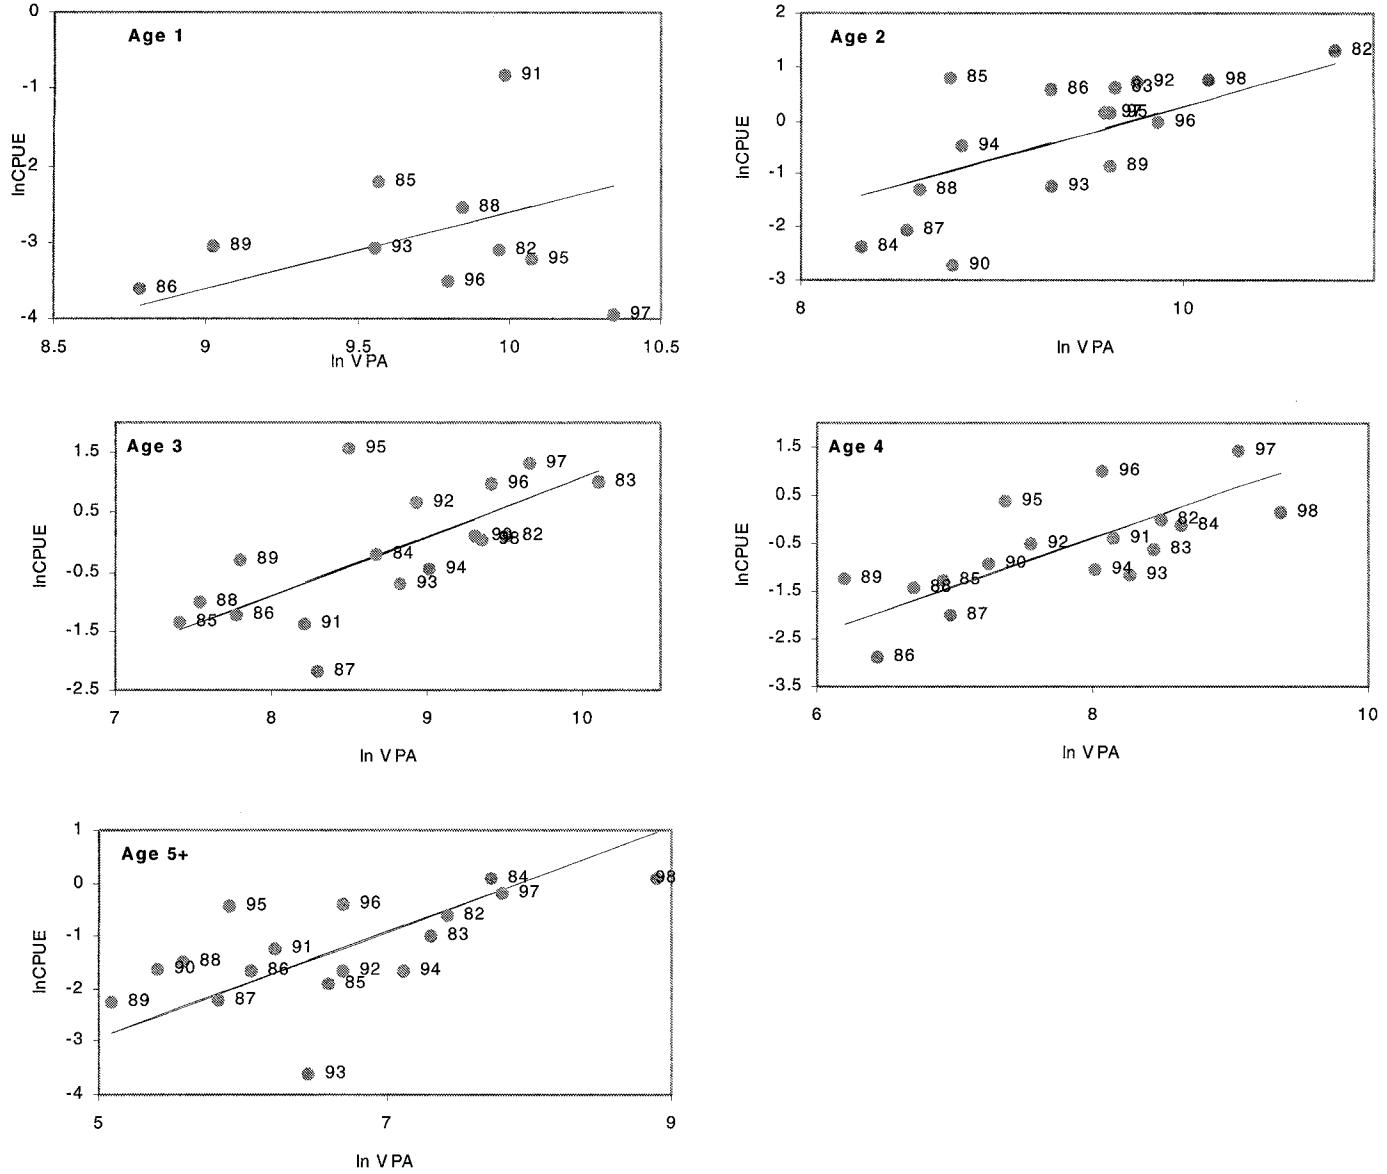

Fig. 21. Age by age residual plots for the NMFS spring survey (Yankee 36), Georges Bank yellowtail flounder.

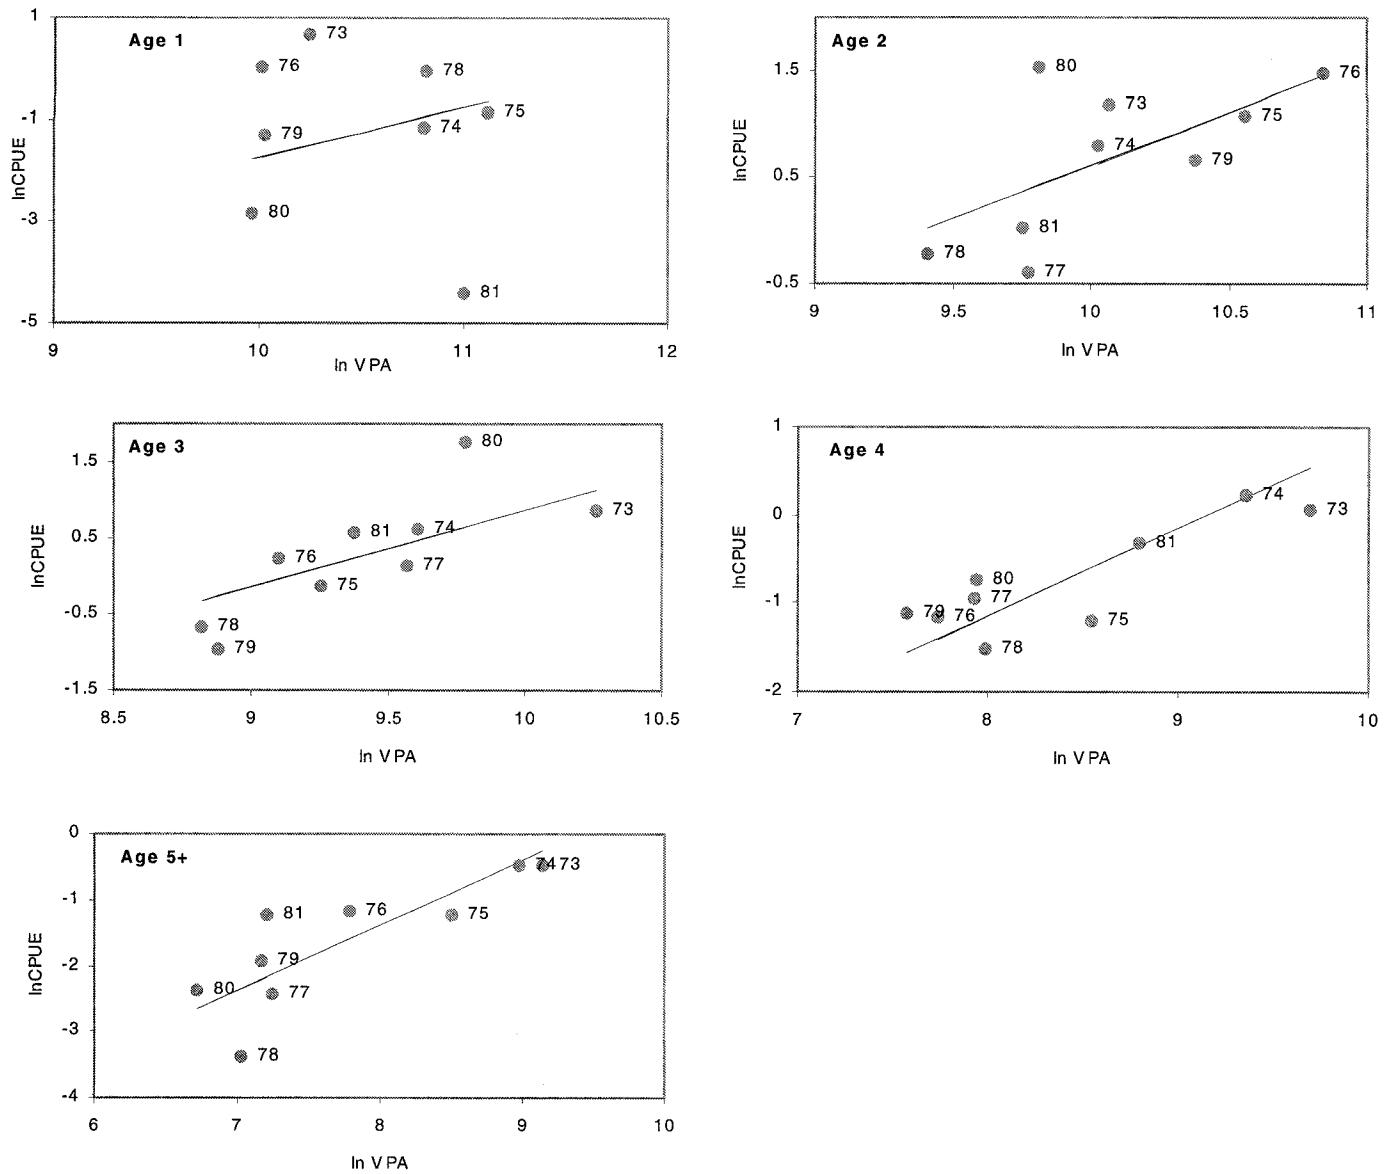

Fig. 22. Age by age residual plots for the NMFS spring survey (Yankee 41), Georges Bank yellowtail flounder.

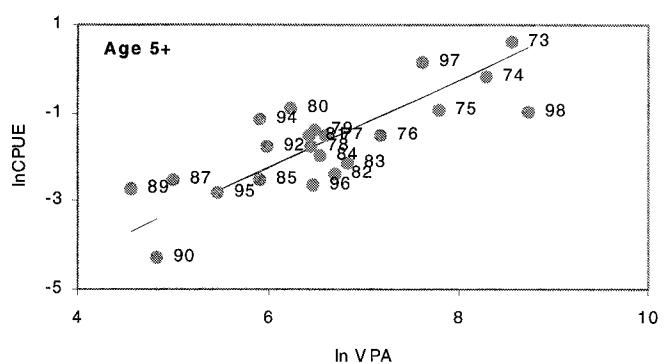

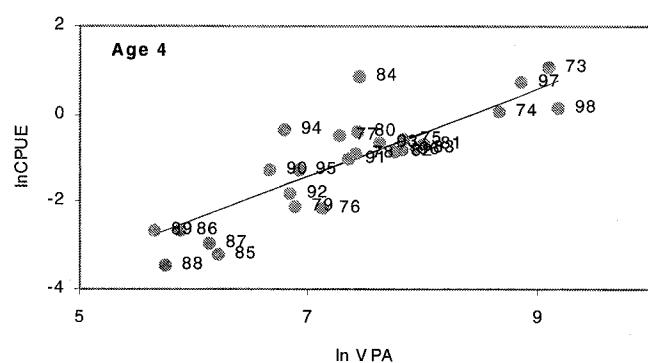

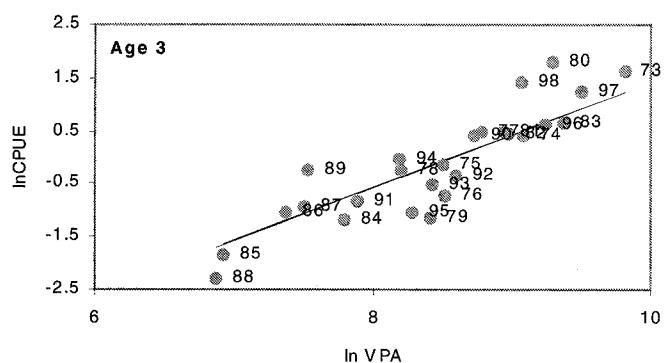

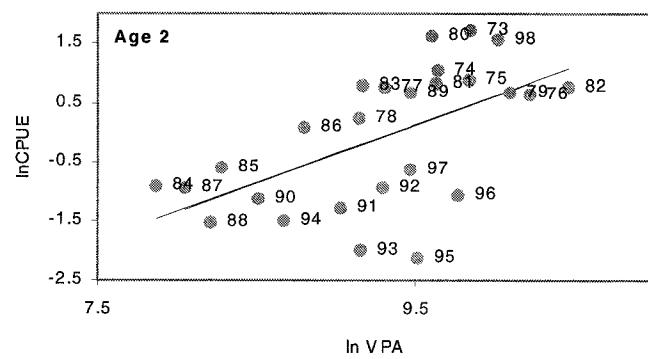

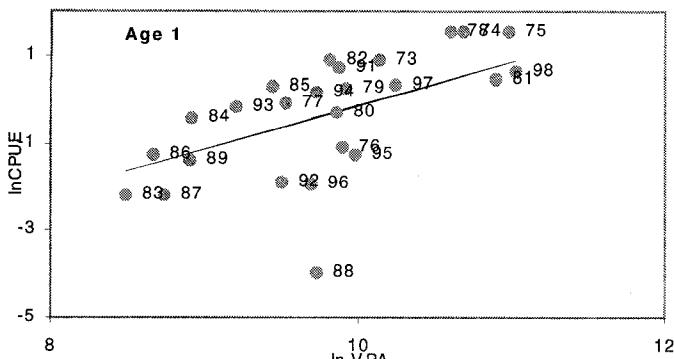

Fig. 23. Age by age residual plots for the NMFS fall survey, Georges Bank yellowtail flounder.

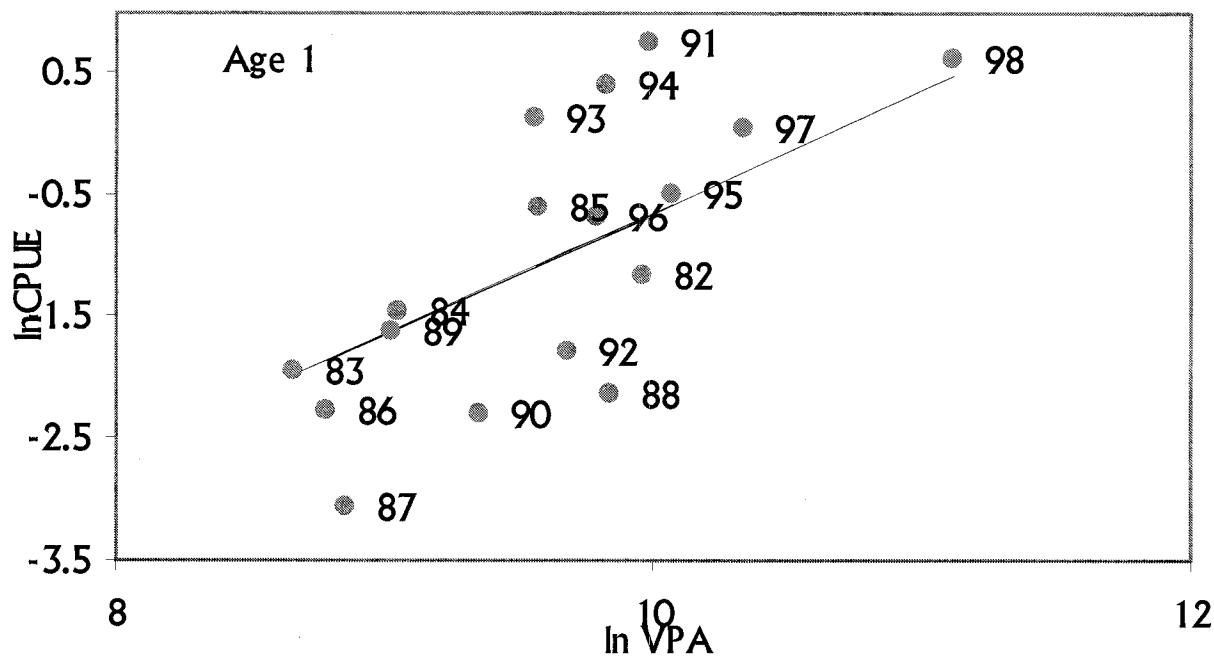

Fig. 24. Age-1 residual plot for the NMFS scallop survey, Georges Bank yellowtail flounder.

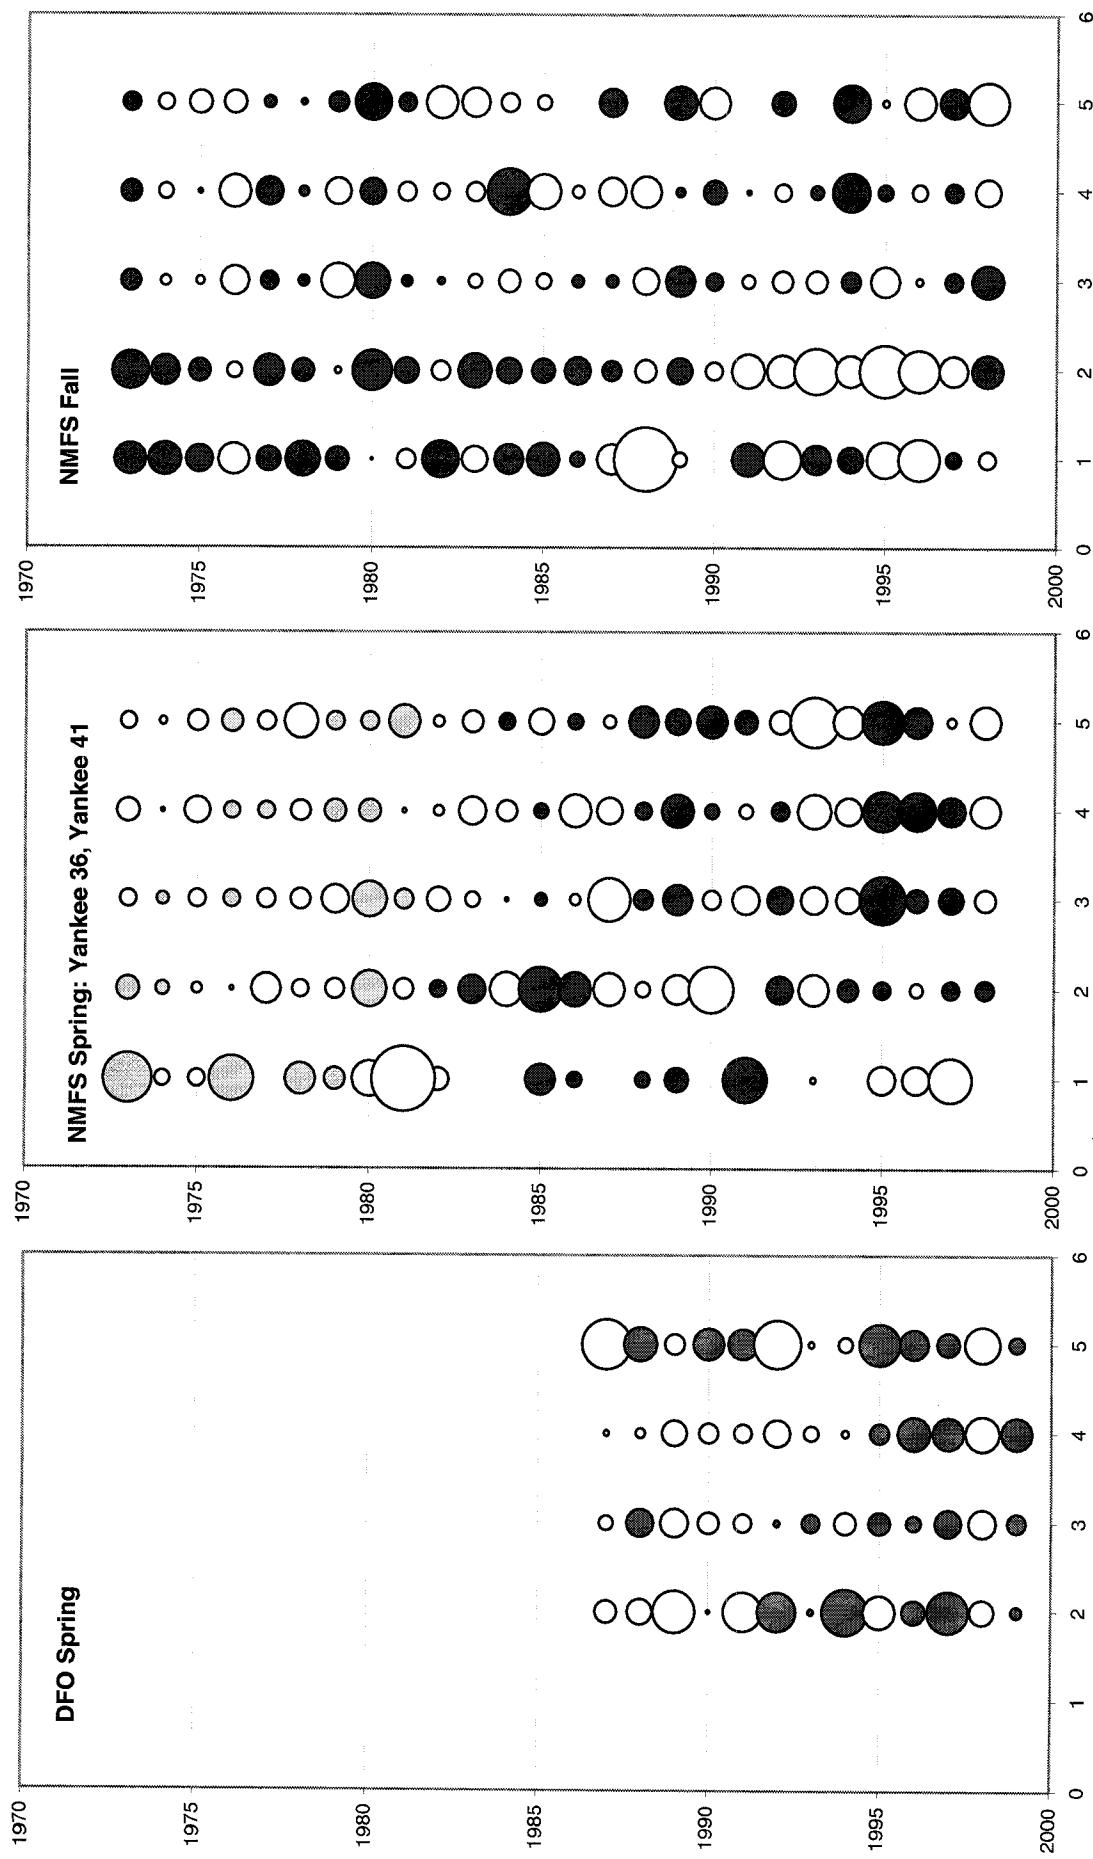

Fig. 25. Bubble plots where the area of the bubble is proportional to the magnitude of age by age residuals for the relationships between ln abundance index versus ln population numbers, Georges Bank yellowtail flounder. The grey shaded symbols in the NMFS spring series denote the period when the Yankee - 41 net was used. The open symbols denote positive residuals, and closed symbols denote negative residuals. Refer to Figs. 20-23 for the absolute value of the residuals.

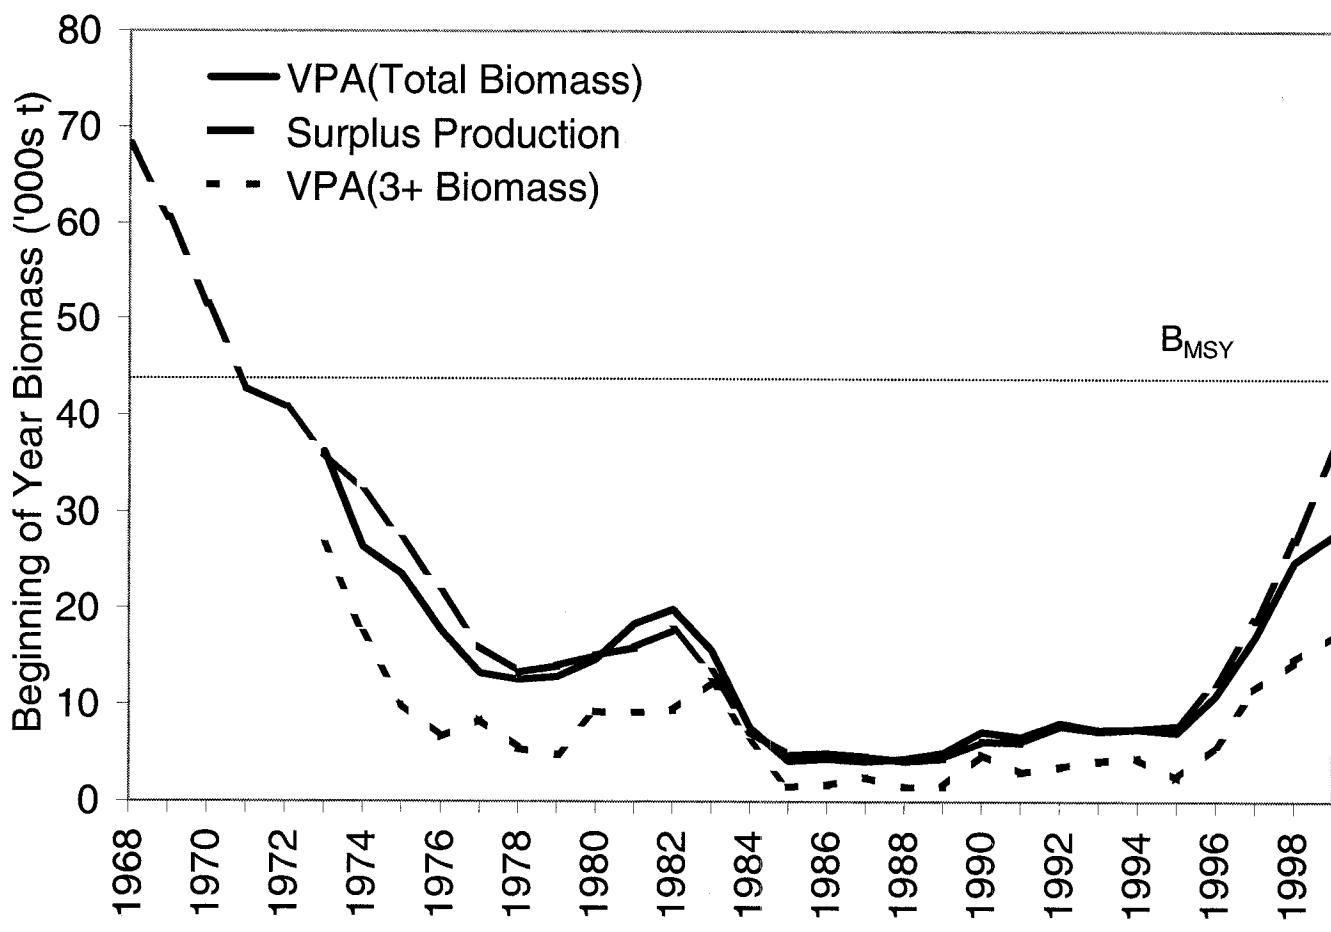

Fig. 26. Trends in total beginning of year biomass ('000s t) as indicated from the VPA and surplus production model, yellowtail flounder on Georges Bank. The biomass values in 2000 are projected assuming  $F_{0.1}$  fishery removals in 1999. The  $B_{MSY}$  level of 43,360 (from the surplus production model) is also shown.

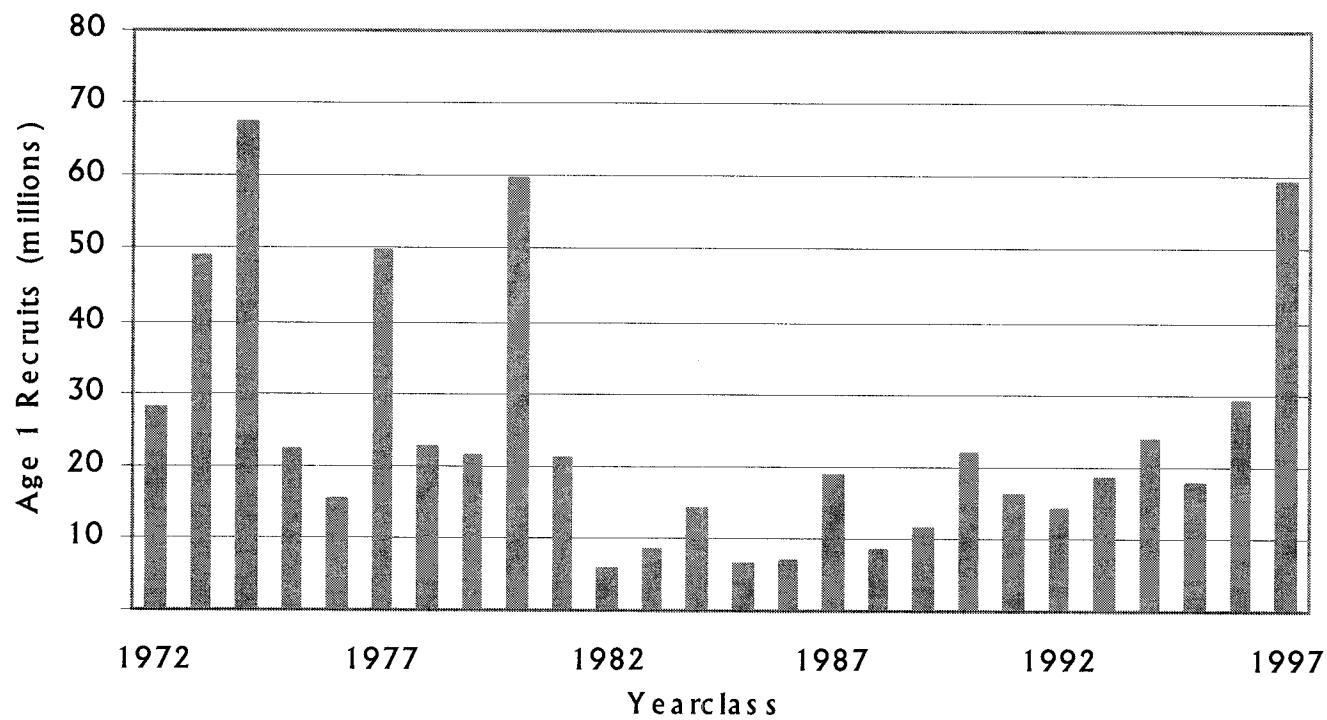

Fig. 27. Trend in age-1 recruitment, Georges Bank yellowtail flounder, 1972 – 1997.

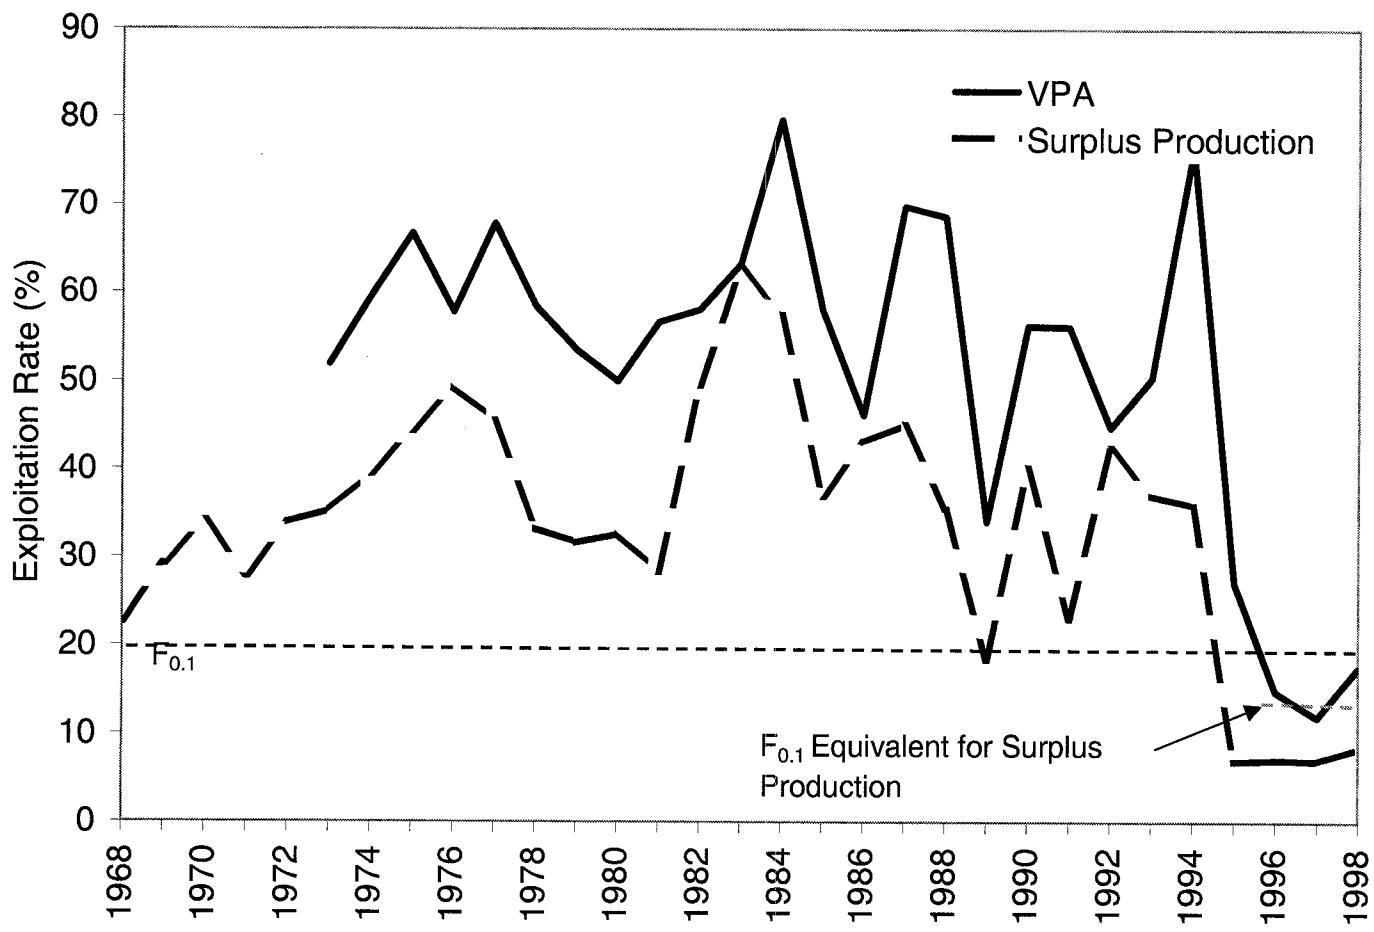

Fig. 28. Trends in 3+ exploitation rate (%) from the VPA and total exploitation rate from the surplus production model, yellowtail flounder on Georges Bank. Reference levels are also shown.

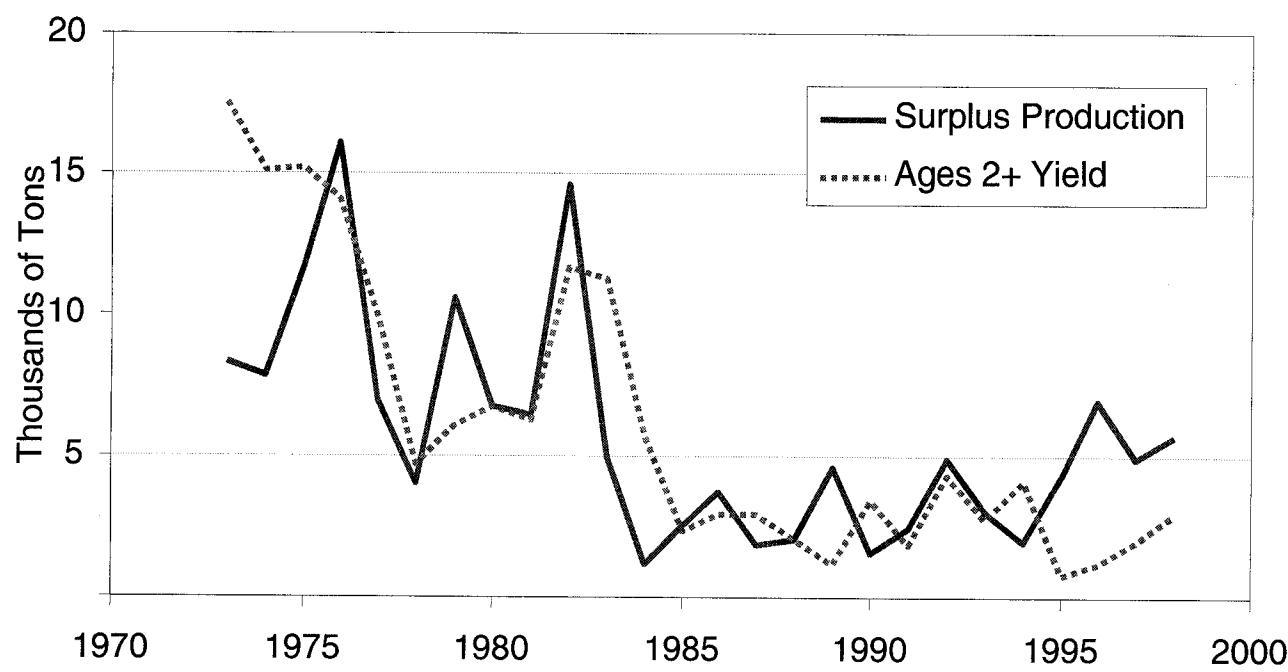

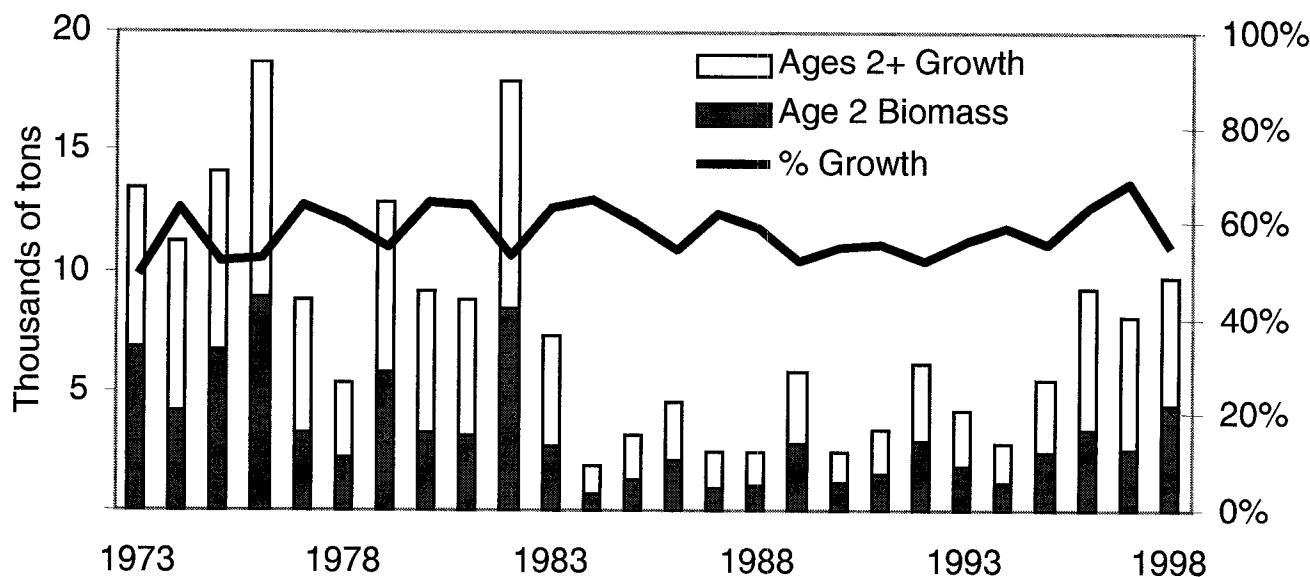

Fig. 29. Components of production (top panel), and production as indicated by the VPA, compared with fishery yield, Georges Bank yellowtail flounder.

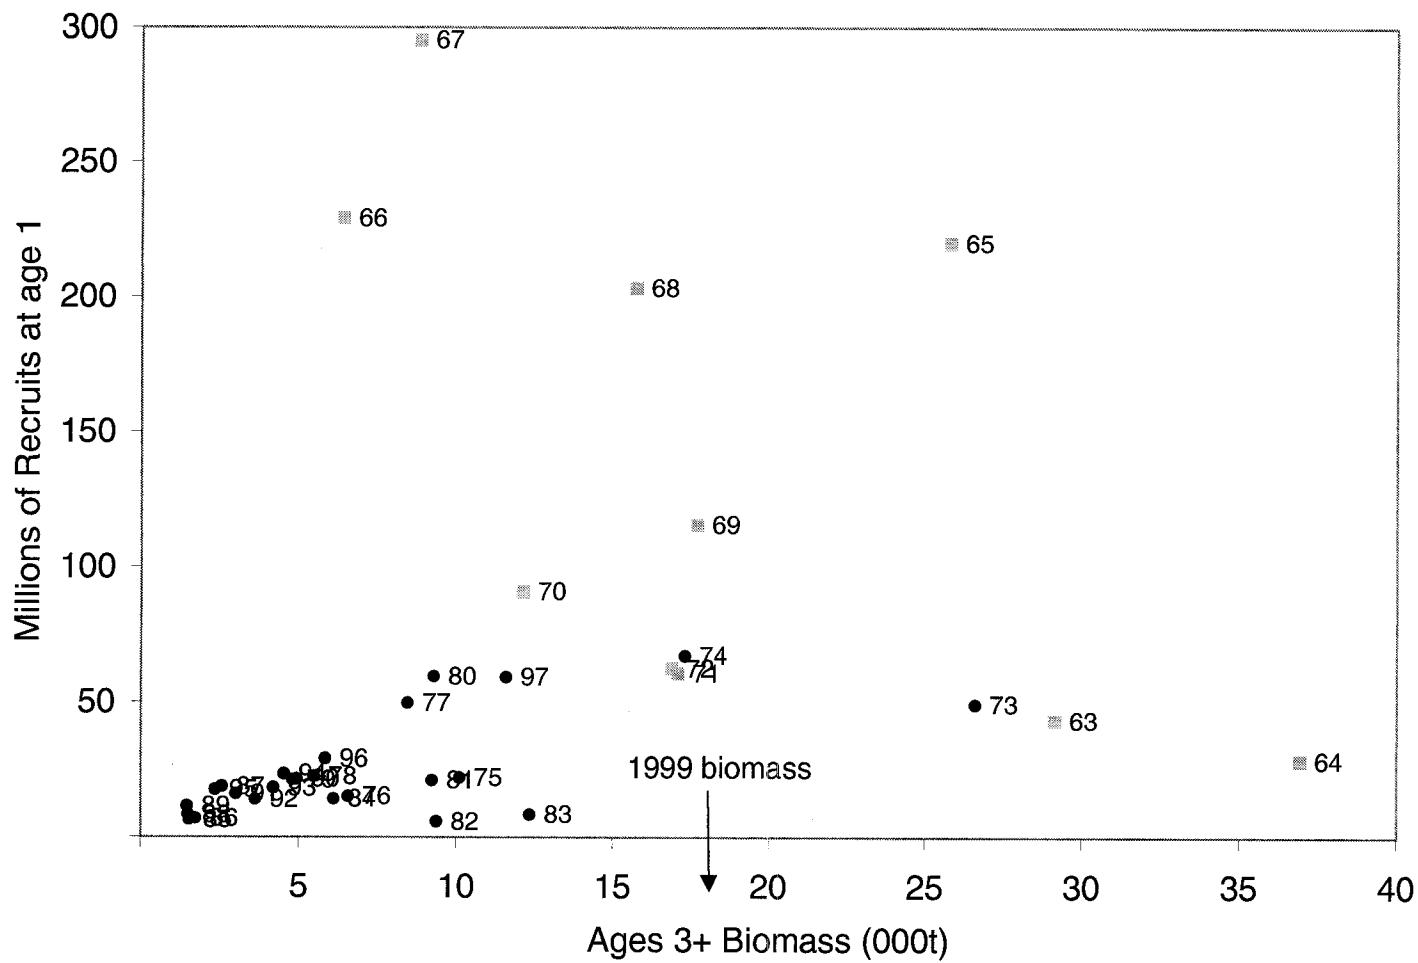

Fig. 30. Total biomass (000s t) and age 1 recruitment (millions) relationship from the VPA, Georges Bank yellowtail flounder. The current beginning of year biomass from the VPA is also shown.

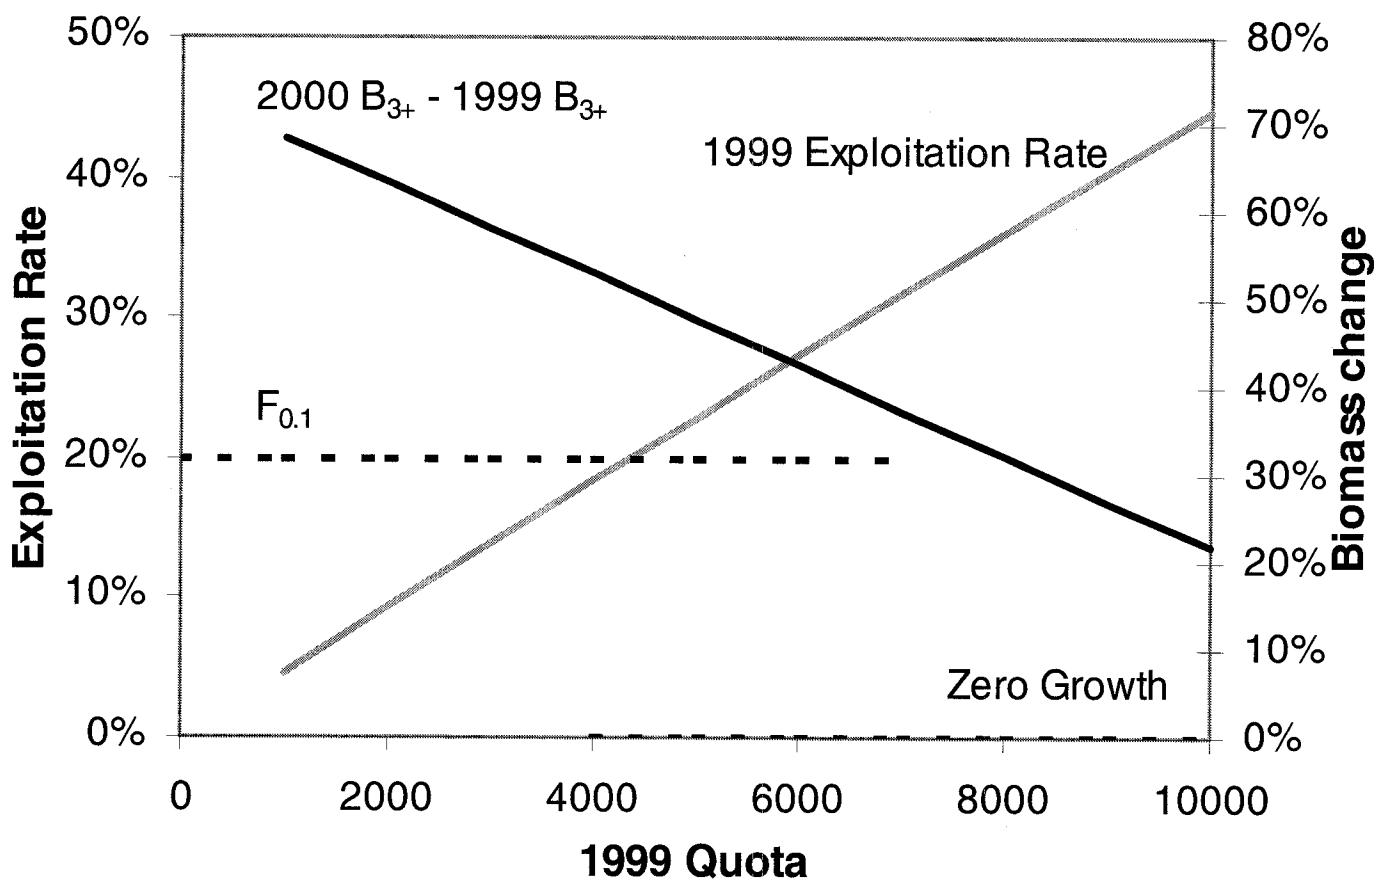

Fig. 31. Implications of various 1999 quotas (combined Canada and USA) on exploitation rate and change in the 3+ population biomass from 1999 to 2000.

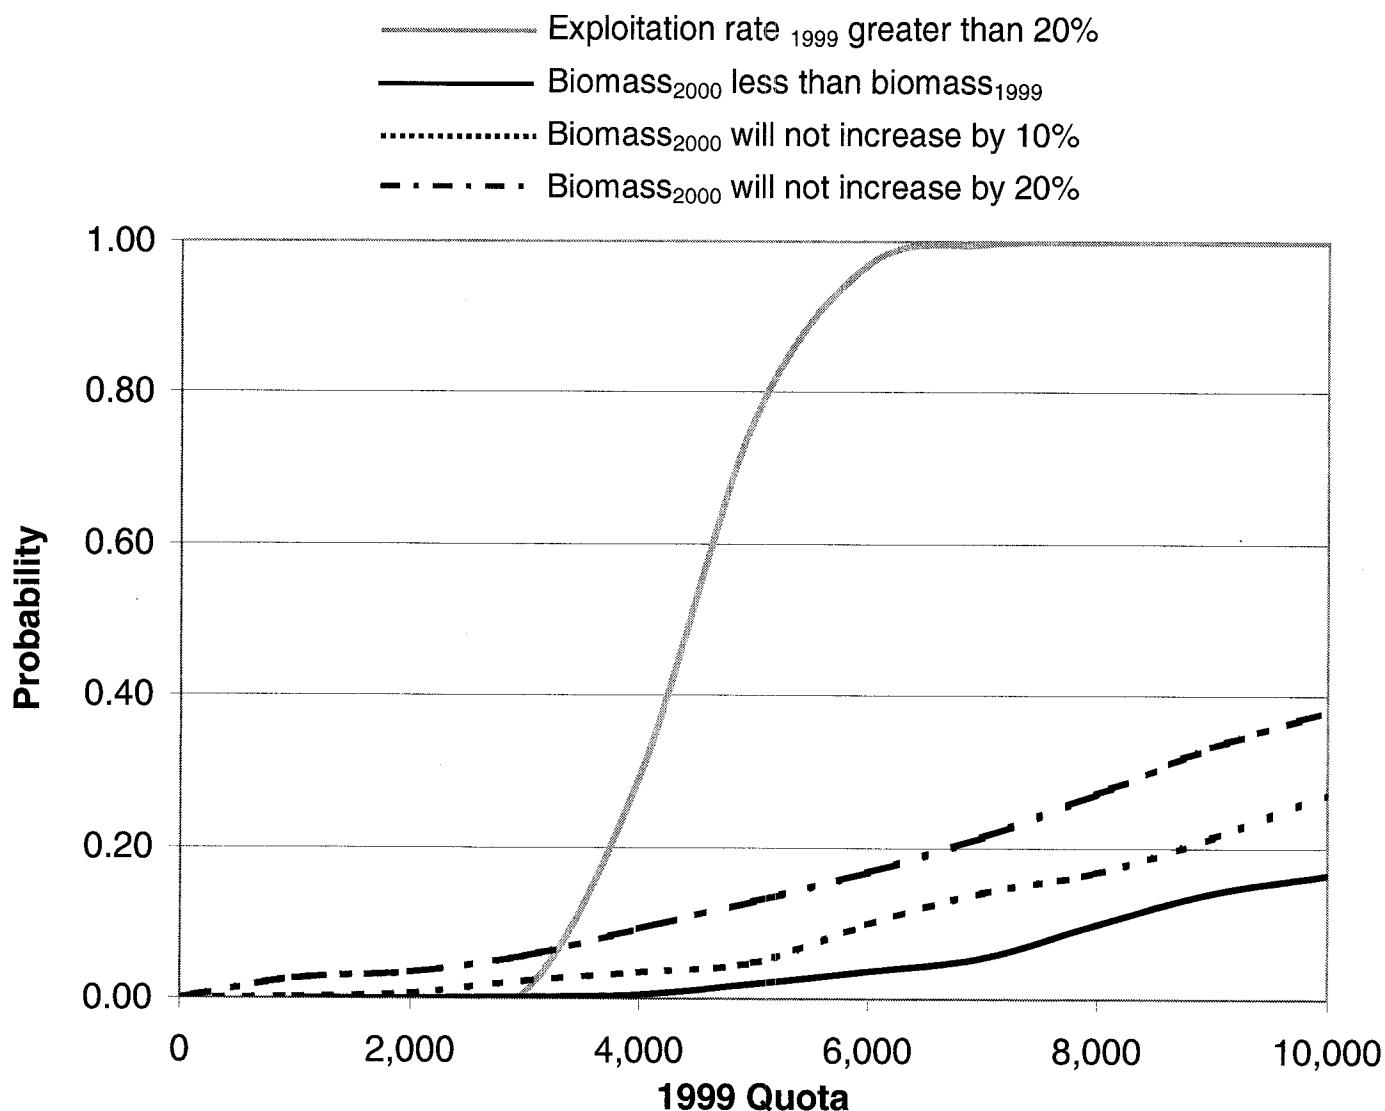

Fig. 32. Risk of exceeding the  $F_{0.1}$  fishing mortality or not achieving increments of population biomass growth at various quotas for the 1999 fishery, Georges Bank yellowtail flounder.
